NEW ENGLAND SURGICAL SOCIETY

A FORM OF SCLEROSING OSTEOMYELITIS FOLLOWING FRACTURES OF THE LONG BONES*

BY PAUL P. SWETT, M.D.†

BY a singular coincidence it was my lot to see three peculiar and previously unheard of cases of pain and disability following fractures of the long bones at about the same time. All of them presented certain similarities which seemed to link them into a single group. In two of these the fractures occurred in the shaft of the tibia and in the third the shaft of the second metatarsal bone. Symptomatically these patients complained of disabling pain long after the fractures had united. Physical examination showed local edema of the soft tissue surrounding the sites of the fractures, and local tenderness, and the x ray showed an obliteration of the medullary portion of the bone for a considerable distance at the fracture site. These three patients shared the accusation of malingering. Both men had been denied further compensation insurance benefits on the basis that they were able to work, and the woman was thought to be brazenly malingering. A search of the literature has not brought to light a single reference to the condition from the clinical side though there are a few obscure pathological references. Hence it seems appropriate to report these cases in some detail, and to follow this with a discussion of the pathology.

CASE 1. H. R. A young man aged twenty-seven years married in good health formerly employed as a lineman by the Western Union Telegraph Company was referred to me January 24, 1933 by Compensation Commissioner Donohue because of pain and disability involving the right leg following a fracture sustained while at work on October 7, 1932 when a pole fell on his leg. Following this injury he was treated in a hospital for ten weeks during which time the leg was immobilized in a circular plaster case. At the end of twenty-one weeks he resumed his former work but he could not long continue it because of constant pain near the fracture site. He noticed that his leg was bowed when he resumed his work and he felt that the bowing increased as time went on.

The examination showed him to be well developed and nourished and healthy appearing mouth and throat were negative heart sounds normal blood pressure 122/86 abdomen negative reflexes normal. The right leg showed an old healed fracture of the tibia and fibula in the mid portion which had united

with considerable external bowing and an inch and one-eighth of shortening. He had good motion in the knee hip and ankle. He had no limitation in straight leg raising of either thigh normal range of motion in both hips knees and ankles. He referred the origin of his discomfort to the fracture site in the mid-portion of the tibia both legs were moderately bowed but the right leg was unquestionably more bowed than the left.

X rays at that time were reported by Drs. Roberts and Ogden as follows:

"The x ray examination of the right leg shows evidence of old fractures of the tibia and fibula in their middle thirds. The fragments of each bone appear firmly united at this time with abundant callus formation. The lower tibial fragment is displaced to antero-external aspect fully one-half the width of the shaft and the fragments show a slight degree of postero-external angulation. The lower fibular fragment is displaced completely to antero-external aspect with slight overriding."

Although this patient was a compensation case he was not interested at the time I saw him in securing a permanent partial disability settlement but he was anxious to have some type of treatment to relieve the pain in his leg. I came to the conclusion that the pain resulted from the strain secondary to the bowing and the shortening and that the only effective plan that we might pursue to relieve this pain would be to do a corrective osteotomy above the fracture site. I suggested that if the patient objected to so radical a procedure, it would not be unreasonable to let him try the effect of balancing his shoe in such a manner as to relieve some of the strain.

We tried this for approximately six weeks, but on March 14, 1933 the patient said that he could not see that there was any improvement and that the leg troubled him so much that he was not able to work continuously and I therefore arranged for the corrective osteotomy.

This procedure was carried out on March 20 and the following operative note was made at that time:

"The purpose of the operation was to correct a bowleg deformity resulting from an old fracture at about the mid portion of the right tibia and fibula. The fracture had been of the oblique type and while it was solidly united there remained a considerable degree of external bowing a slight degree of posterior bowing and some degree of internal rotation of the distal fragment. Through a three inch longitudinal anterior incision we did an oblique osteotomy of the tibia slightly above the fracture site and through an external longitudinal incision we did a transverse osteotomy of the fibula at the same level. The wounds were closed in layers without drainage the leg was manipulated into as nearly

Read at the Annual Meeting of the New England Surgical Society at Manchester N. H. September 22, 1934.

†Swett, Paul P. — Attending Orthopedic Surgeon, Charlotte Hungerford Memorial Hospital, Torrington. For record and address of author see "This Week's Issue," page 2.

correct alignment as possible and immobilized in this corrected position in a circular plaster case extending from the toes to the mid thigh "

By July 20 the following note was made

"The alignment of his leg is perfect. He appears to have solid union at the osteotomy site. New x rays made today confirm this clinical observation. I have, therefore, advised him that he may discontinue his crutches "

On September 14 our note is as follows

"The alignment of his leg is very satisfactory. There are no signs of inflammatory reaction and while it seems to me entirely reasonable that he may continue to have some pain at the old fracture site, for some little time in the future, I do not think that the extent of his pain now should be of sufficient degree to totally disable him, and I believe his leg is now strong enough to permit his resuming his work "

On October 13, although the patient continued to complain of pain, saying that his leg bothered him just the same as it did before the corrective osteotomy, I made the following note

"My examination of his leg today shows that the general alignment is satisfactory, that there is only a slight increase in the degree of varus of the right leg, as compared with the left, there is no swelling, there is no local disturbance in the circulation. He has a full range of motion in his knee and in his ankle, and there is no reason at the present time that I can see why he should not do his former work "

On November 13 I made the following note

"He has been doing some odd jobs around the past month and he says that the more he does with his leg the more pain he has, that the pain is just the same as it was before I operated upon him and that the pain extends downward from just below the site of the old original fracture in his tibia and he says that at times also, the leg swells and he has tenderness to local pressure and some edema throughout the region of the fracture site. Because of his continued symptoms and because of the edema, I do not see how we can avoid the conclusion that there must be something in connection with the original fracture site which leads to these symptoms and while his leg now looks quite straight, lining up perfectly in comparison with the other leg, I believe we should have new x rays of the entire right leg to see what explanation we can find for these continued symptoms "

On November 23, the x rays were reported as follows

"The x ray re-examination of the right leg now shows firm appearing and rather dense union throughout tibial and fibular fracture sites. The position of the fragments remain approximately the same as last noted "

And I found that the patient still had a distinct area of local edema at the original fracture site in his tibia

On reviewing his last x rays I was impressed by the fact that he has an unusually extensive degree of sclerosis of the medulla at each side of the fracture site. Basing my decision, therefore, on this x-ray observation, the patient's apparently sincere complaint of continued pain, the presence of the local tenderness and the undoubted local edema, I have concluded that we are dealing with a painful condition which

either is similar or at least is analogous to, a sclerosing type of osteomyelitis. I believe that we should operate at the original fracture site for the purpose of opening the medullary area on both sides of the old fracture site in an effort to overcome the sclerosis and reopen the medullary channel to relieve the tension and consequent pain "

This operation was carried out at the Hartford Hospital on December 4, and the following operative note was made

"Operation was for the purpose of doing a decompression of the medullary portion of the tibia at the site of a fracture at about the junction of the lower and middle thirds of the tibial shaft. The original fracture fragments were oblique and had united in position of considerable external bowing. The patient had persistent pain at the fracture site accompanied by local edema of the soft tissues and this pain had not been relieved by an osteotomy done several months ago above the fracture site for the purpose of correcting the alignment of the leg. On this occasion we exposed the original fracture site through a four inch anterior longitudinal incision. We took out a slot of bone approximately one inch in length on each side of the original fracture site and we found that for a distance of more than an inch on each side of the fracture line the medulla had been replaced by cortical bone. After we had removed about two inches of the anterior surface of the tibia approximately one-half inch in width we were able to break through into the medullary cavity at each end and thus to establish a communication again. Wound was closed in layers without drainage and the leg was immobilized in a circular plaster case extending from the toes to the knee "

The pathological report follows

"R— Diagnosis Focal necrosis of bone

Macroscopic Specimen consists of many fragments of bone tissue in part dense cortical type, with some areas of cancellous bone

Microscopic The decalcified sections show in part dense cortical bones of essentially normal structure. The marrow spaces are largely filled with fat. There is no obvious proliferation of bone tissue. There are, however, several areas of necrosis with an amorphous blue staining granular debris not associated with inflammatory reaction. There is no evidence of neoplasm "

Following this procedure the patient appeared to make an uninterrupted recovery and the following note was made

"His leg pains are less but he notices that, since he discontinued the crutches, he has had a little buckling sensation in his knee when it is hyperextended

"Examination of his knee suggests the possibility of a slight amount of thickening of the infrapatellar pad. The alignment of his leg is normal, the wound is beautifully healed, there is no local edema or hypersensitiveness and a normal range of motion in his ankle joint. He has full flexion and full extension in his knee joint

"It seems to me that except for some degree of weakness in his leg resulting from disuse, he has made an excellent recovery. I think he has convalesced now to a point where he is able to resume his work and I do not believe it will be necessary for me to examine him

again, and I anticipate he will have a very satisfactory result.

The last time I heard from him in July 1935 he said his leg was entirely well and he was applying for a job as a state policeman.

CASE 2 A. S. a man of forty-eight married in good health formerly employed by the Connecticut Quarry Company was referred to me on December 1 1933 by Attorney Richard Deming because of pain and swelling in the left leg following a fractured tibia and fibula sustained while at work on August 10 1932 when a stone fell and struck his left leg above the ankle causing the fractures. Following this injury he was treated in a hospital, first by skeletal traction with a pin in the heel and then a cast was applied. On May 22 1933 he resumed work but was unable to continue after the second week on account of pain and swelling in his leg. If he made a misstep his leg bothered him.

Examination showed him to be well-developed and well-nourished and healthy appearing. He had two upper crowned teeth and one retained lower root. Throat was negative. Heart sounds were normal. Blood pressure 136/100. Abdomen negative. His patellar reflexes were normal. There was a fracture of the left tibia at the junction of the lower and mid thirds which had united with some inward displacement of the distal fragment the alignment was good. There were edema and tenderness present at the fracture site. There was no false point of motion and no real limitation in ankle joint motion. The patient had bilateral bowleg but it was less marked on the fracture side than on the sound side.

X-rays made at that time by Doctors Roberts and Ogden were reported as follows:

The x-ray examination of the lower two-thirds of the left leg including the ankle shows an oblique fracture through the tibia 9 cm above the distal end. Firm bony union has taken place with the lower fragment displaced to the inner side approximately one-third its width. There is an oblique fracture through the fibula at the same level. Firm bony union likewise has taken place here with the lower fragment displaced to the inner side over one-half its width.

The arteries throughout the region examined are moderately calcified.

I reviewed these films and while I was in agreement with the above findings it seemed to me that there also was an additional factor in connection with the unusually extensive degree of sclerosis for a considerable distance at each side of the old fracture site involving the whole medulla in this area and preventing the normal communication within the medullary cavity between the distal and proximal fragments. This fact taken in conjunction with the patient's complaint of continued pain and the presence of local edema in the neighborhood of the fracture site led me to the conclusion that he had a considerable degree of disability and continued pain, and while the patient unquestionably exaggerated the extent of his disability somewhat, I was inclined to think he should be given the benefit of the doubt and that his tibia should be operated upon for the purpose of reestablishing the communication between the medullary cavity of the upper fragment and the lower fragment.

The patient was operated upon on April 23 and the following operative note was made:

"The operation was for the purpose of reestablishing the medullary canal where it had become blocked off at the site of a fracture at

about the junction of the middle and lower thirds of the left tibia because the patient had local edema and tenderness constant pain and occupational disability. We exposed the area through a four inch anterior longitudinal incision. We found the periosteum very thick and dense and perhaps four times as dense as normal. We removed a slot from the anterior cortical surface approximately three inches in length and we found that for a distance of approximately three-fourths of an inch in the mid portion of this slot the medullary canal was completely blocked by dense burnt bone. The removal of the slot restored medullary communication. The periosteum was carefully closed over. The skin was closed with silk and the leg was immobilized in a circular plaster case extending from the toes to the knee."

Following this procedure the patient appeared to make an uninterrupted recovery until on June 7 1934 the following x-ray report was made:

"The x-ray reexamination of the left leg shows evidence of surgical procedure along the inner aspect anteriorly of the tibial fracture site with an absence of a portion of cortical bone along this area and also an apparent absence of a portion of the medulla with a cavitation now formed extending from the upper to the lower fragment, through the fracture site. All fragments remain firmly united as formerly noted. Through out the medullary portion of the operative site, there are a few small fragments of bone. Otherwise the findings are negative."

The pathological findings were as follows:

A. S. — Diagnosis: Focal necrosis of bone. Macroscopic. Specimen consists of many fragments of bone chips together forming a mass about 3 cm in diameter.

Microscopic. Sections show largely a cancellous type of bone. The trabeculae appear somewhat thickened and rather irregular. There is no neoplastic proliferation. Marrow spaces are largely filled with fat though in some places there appears to be increased vascularity. There are one or two small areas of degeneration with amorphous calcium deposit not associated with inflammatory reaction. No evidence of malignancy.

On July 6 I made the following note:

He seems to have made a practically complete recovery. There still is a little tenderness and a little edema in the region of the scar. He is to discontinue the cane discontinue the bandage and he may resume work.

On November 30 1934 he wrote that he wanted me to know that the leg was all right.

CASE 3 F. K. a young woman of twenty-three in good health employed at the Windham County Hospital, was admitted to the hospital on November 16 1933 because of pain and swelling on the dorsum of the right foot which she began to notice about six days before her admission. Three or four weeks before her admission she had run the wheel of a hospital bed over the dorsum of her right foot but thought very little of the accident at the time although for two weeks afterward she had difficulty in walking particularly up stairs. She had no symptoms indicative of arthritis no history of chills and no swelling in the groin or leg.

Examination showed a well-nourished girl. Her pupils were equal. Tonsils had been removed there was no general adenopathy. The heart was not enlarged and there were no murmurs. Abdomen was negative. Lungs were clear and resonant. Examination

tion of the foot showed marked swelling and tenderness over the dorsum of the foot, there was a suggestion of an ecchymotic area in this region

X-rays made on November 14 showed no evidence of fracture or dislocation. There were no localizing signs of tumor or disease, nor was there any evidence of foreign body.

On November 27, 1933 a reexamination of the right foot is reported as follows:

"Reexamination of the right foot now shows some periosteal new bone along the margin of the distal third of the shaft of the second metatarsal. There is a very slight amount of bone destruction on the internal side of the shaft in this area and in the soft tissue there is a shadow approximately one-half cm in thickness which is just surrounding the first mentioned portion of the shaft. There is also considerable soft tissue swelling over the dorsum of the foot. These findings are thought to be due, first, to an osteomyelitis, probably tuberculous in origin, secondly, to lues and third, to neoplasm. The first is thought much more probable."

On November 29, 1933 it was decided to explore the region and the following operative note was made:

"Under gas-oxygen anesthesia a small incision was made over the distal end of the second metatarsal and after going through the skin a cavity was entered which was lined by necrotic and broken down tissues with some old blood clot. The appearance of the cavity suggested tuberculosis. No frank pus was encountered. The incision was carried down to the distal end of the shaft of the second metatarsal bone and here the periosteum was found to be stripped and the bone to be roughened. A specimen of the bone was removed for pathological diagnosis as well as the tissue lining the cavity. Boric ointment drain was placed to the center of the wound."

Following this procedure the patient had a fairly satisfactory convalescence with gradual improvement until she was discharged on January 12, 1934.

The pathological findings were as follows:

"F K.—Diagnosis: Bony fragments, adipose tissue with organizing exudate and hemorrhage.

"Gross: The specimen consists of several small pieces of tissue said to be curettings from the second metatarsal bone of the right foot. They are irregular, the largest being approximately 2 cm in length. All the fragments are firm and pearly white. The entire specimen is preserved for microscopic study.

"Microscopic: The preparation consists of several fragments of osseous tissue the marrow of which has been replaced by a thin network of connective tissue which contains a very slight sprinkling of small round cells of adipose tissue scattered throughout which are large areas of fresh extravasated blood and slight sprinklings of small round cell infiltration. Many of the areas of hemorrhage appear altered and extending into them are proliferations of fibroblasts and capillaries."

Postoperative x rays are reported as follows:

"December 20, 1933—Reexamination of the right foot shows a marked increase in the amount of calcium laid down in the area previously described at the distal end of the shaft of the metatarsal to the second toe. This has the appearance more of a chronic granuloma rather than osteomyelitis of pyogenic origin.

"January 3, 1934—Reexamination of the right foot shows very little change since the previous examination except that more calcium has been laid down on the distal third of the shaft of the second metatarsal. There are still some areas of bone loss, some of which very closely simulate a fracture through this area."

The following is a copy of a letter from Dr M C Sosman, to whom the x-rays were sent:

"Your films show a very peculiar form of osteitis and periostitis of the distal end of the second metatarsal. It is hard to reconstruct the progress of events from these films but one can see that there was no evidence of fracture or osteomyelitis November 14, that there was a definite periostitis November 27 with healing December 20 and January 3. It is conceivable that this lesion began as an infected hematoma on or around the bone, later involving the bone. It does not look like tuberculosis and there is no evidence that it is Madura foot. I should expect the process to subside without further complications."

On February 20, 1934 this patient reentered the hospital. She had gradually improved after leaving the hospital and had returned to work, but three days before readmission she began to have a return of pain and swelling on the dorsum of the foot.

X-ray reexamination showed very little change in the size and shape of the calcareous deposit around the distal third of the shaft of the second metatarsal since the previous examination.

On April 11 I was called in consultation and made the following note:

"I saw this patient in consultation with Dr Ottenheimer. I was informed that after I saw her previously in January the wound healed and her febrile reaction ceased so that she returned to her home for a month and got along very well until the pain and swelling recurred and since then she has been in the hospital with pain, swelling and edema on the dorsum of her foot and the maximum local tenderness is over the second metatarsal. X-rays of her teeth and sinuses have been made and are negative. Wassermann is negative, and test for undulant fever is negative. New x-rays of her foot, made on the 26th of March, appear to show the process healing. In view of the absence of any other apparent cause for her fever and because of the persistent swelling and thickening and local tenderness, I advised another operation and this operation was carried out at the hospital on April 13. Assisted by Dr Ottenheimer, I exposed the site of the lesion of the second metatarsal through the previous incision, somewhat enlarged. We removed from the dorsal surface of the metatarsal quite a thick plaque of very pale appearing dense fibrous tissue which seemed to be partially calcified. We also removed enough of the cortex of the bone directly underneath this mass of tissue, so we could establish normal communication on both sides of the medullary cavity. The wound was closed in layers without drainage and the removed tissue was sent to the laboratory for further examination. Judging from this experience and what I could see in the gross specimen, the condition would seem to have been one of mild chronic periostitis of the metatarsal bone."

The pathological findings are reported as follows:

"Gross: The specimen consists of a number of small fragments of yellow-white tissue most of

which is adherent to bone. The bone is stripped from one of the fragments of tissue and the soft tissue sent through for immediate microscopic preparation. The remainder of the specimen is preserved for decalcification and later microscopic preparation.

"Microscopic Preparation consists of fragments of osseous tissue. The bony lamellae are rather broad and show well formed haversian systems. The marrow spaces are filled with a rather loose fibrillar connective tissue with a considerable number of adipose tissue cells scattered throughout. No islets of blood forming cells are seen. The bone lamellae are thicker in some places than in others. In some areas the surface of the bony fragment is covered by peristroma. No evidence of atypical proliferation is noted. No collagen infiltration is noted anywhere in the preparation.

"Diagnosis Fragments of osseous tissue.

Following an uneventful convalescence and recovery the patient was discharged from the hospital on May 19, 1934 using crutches.

On December 28, 1934 Dr. Ottenheimer wrote:

"You might be interested to know as a follow up note on Miss K. that she has made a perfect recovery. She is now working again in our hospital and has no limp or any pain or swelling in the foot and her general physical condition apparently is good."

While it is true that there is very little clinical record of such a condition as these three cases represent, fortunately there is some light thrown upon it by the pathologists and this serves to corroborate the authenticity of these clinical findings.

Adam and McCrue Textbook of Pathology Lea & Febiger 1912 p. 682 classify chronic osteomyelitis as showing two forms: 1. Rarefaction or osteoporosis. 2. Condensation or sclerosis. Condensing osteitis occurs where the irritation is not so intense. One of two events may occur. Either there is evidence of increased osteoblastic activity so that the lamellae undergo progressive thickening and the marrow spaces reduce or the marrow first becomes less cellular, shows an increased fibrosis and the cells of this fibroid tissue undergo metaplasia becoming bone corpuscles. In this way the whole of the marrow may become converted into dense bone.

Kantmann's Pathology trans by Reimann Vol. 2 P. Blackiston's Son & Co. 1929 p. 1106. Osteitis (necrotic endostitis) Ossification. Condensing Osteitis Osteosclerosis.

Direct antithesis of osteoporosis.

Consists of formation of new at first osteoid then calcified true bone changes, coming from the marrow and vessel cavities and encroaching upon the old trabeculae. The spaces within the bone are filled with more and more bone tissue. This type of osteitis ossificans may lead to stony hard thickening, sclerosis and eburnation. Volkman differentiates a restitutive reactive or inductive and idiopathic bone sclerosis. The restitutive sclerosis sometimes follows a rarefying osteitis. The closure of marrow cavities after fractures in amputation attempts in the space left by discharged sequestra is due to this osteomyelitis ossificans. It may follow chronic central osteomyelitis with the formation of sequestra. It always occurs in the neighborhood of bone abscesses or may follow a leg ulcer or a chronic suppurative arthritis.

Geschlechter and Copeland Tumors of Bone p. 662, 1931 refers to Garré's non-suppurative osteitis.

The lesion is solitary and usually affects the tibia. Pain is not severe but may be aggravated by exertion and is often worse at night. It starts abruptly with fever and leukocytosis subsides rapidly into a chronic course extending over a period of years. The medullary cavity is narrowed or obliterated and the cortex thickened and its density increased. It is the result of a low-grade infection in the lymphatics of the bone which brings about an increased fibrous and fibro-ossous proliferation.

These three cases form a group presenting common characteristics which seem to warrant their inclusion in a single clinical entity. These characteristics include a fracture, solid bone union, persistent pain, lameness, occupational disability, local tenderness, local edema, x-ray evidence of a sclerosis of the bone throughout the original fracture site and extending across the medulla, and recovery following the operative reestablishment of the medullary canal between the upper and lower fragments. In addition the microscopic appearance was similar and apparently in the nature of a focal necrosis of bone.

The similarity between this condition and the sclerosing osteomyelitis of Garré led to the trial of the operation, and in every instance the effects were as striking as they are in the Garré cases. It is assumed that the condition is one of local sclerosis so extensive as to invade and block the medulla. In Garré's type the irritative process is held to be a sluggish localized osteomyelitis accompanied by a simultaneous process of repair and thus culmination results in a sclerosis extending across the medulla. The pain and local edema with tenderness indicate the tension within the bone because of the bridging of the medullary canal. The x-ray appearance, the signs and symptoms as well as the effects of operative treatment are so similar in Garré's type and in the cases here discussed that I am led to the hypothesis that certain fractures in the process of healing may respond to the irritating presence of minute areas of sterile necrosis resulting from the trauma that caused the fracture in the same manner as occurs in response to the irritating presence of a minute localized osteomyelitis in Garré's type of process. So far as the microscopic appearances go, there is considerable support for this theory, and nothing, so far as I can determine, to contradict it.

The practical importance of these observations cannot be overestimated since they make it obligatory for fracture surgeons to prove that a suspected malingerer is not suffering as he complains. This attitude may result in lowering the number of so-called compensation and litigation neuroses conditions that do exist but whose existence we should not allege until we are sure of our ground.

DISCUSSION

DR JAMES WARREN SEVER I was very much interested in hearing Dr Swett's paper

This condition which he has described is apparently a rare one so far as his experience goes, and it is also a rare one in my experience

From the point of view of the industrial surgeon, it seems as if the condition would be one of the greatest importance, and with the many fractures of both bones of the leg which exist in industry, and which come under the control and direction of the various compensation boards, it would seem as if this condition should have been recognized before, and should not by any means be a rare one. It is an interesting thing, that, in relation to fractures of the bones particularly since the various compensation acts have come into effect, it is considered that the anatomical repair is but a prelude to functional restoration of the limb, and the ability of the man to return to work.

Judges and juries today rarely admit cure of a fractured limb, pending acquisition of its complete functional aptitudes. French experts draw definite distinction between "the consolidation surgical" and the "consolidation judicial", or functional restoration.

Interesting and humiliating as it may be, the jurists were the first to realize the true goal of therapy, that is, the restoration of functional capacity following an injury.

These cases of Dr Swett's bring up again the difficult question of the difference between malingering and real functional disability in borderline cases. I can find nothing in the literature after a careful search, which gives one any lead in relation to the conditions which he has found. Faulty anatomical position, alignment and weight bearing of the fragments even when united may well lead to pain and edema and even mild neurotrophic disturbances, which may continue for a long period of time. Faulty alignment and weight bearing, even with normal union, may lead to persistent interference with the circulation and normal muscle pull, and so constitute disability.

Any fracture, of course, particularly one extensive enough to fracture both bones of the leg, may result in considerable injury to the vascular, nerve, and muscle apparatus, and it might well be that the conditions which Dr Swett describes might be in part due to these associated injuries.

Pathologically, repair of fractures of the bones almost always sets up solitary noninfectious, non-suppurative, low grade inflammatory lesions. It is quite easy to understand that destruction of the trabeculae may have a pathological effect on the venous sinuses that are supported by them, causing thinning of the vessel walls, which possess no muscular fibers, and their dilatation and varicosity, transudation and possible rupture. The varicose and dilated vessels are always a constantly active factor with the aid of the forming granulating tissue in which they are enmeshed, in the further rarefaction, and progressive destruction of the bone from pressure necrosis. This constitutes a low grade osteomyelitis, and in spite of the thickening of the cortical bone, and the apparent destruction of the medullary canal, may have been a factor in the causation of the pain and the localized edema.

Pathologically, Dr Swett found dense cortical bone, however, of normal structure, with the marrow space filled with fat. There were several areas of necrosis found in these sections, which make one think that there is a possibility of a noninfectious, low grade osteomyelitis. In some sections, there appeared to be increased vascularity, which might account for the pain and the edema. Granulation

tissue, as you know, is always found as a result of regeneration and reconstruction. Any such a process in bone is always properly termed an osteomyelitis, although there is no evidence presented of pus or pus formation. The fact of the destruction or obliteration of the medullary canal in these cases, I do not believe is the whole factor, but I do believe for some reason or other the presence of granulation tissue and the destruction of the trabeculae in the bone, cause the venous stasis, or congestion, and probably account for the pain and disability in these cases.

The operation on these cases was apparently successful but I believe the condition must be unique, which does not mean, however, that we should not look for it and recognize it when it occurs. It would be interesting in any follow up series, or check up in a number of cases of fracture of both bones of the leg, to have this condition in mind, see how frequently it happens, and whether it recovers spontaneously in any given time. The frank destruction, or apparent destruction of the medullary canal alone, I do not believe, is the sole factor, although the condition seems to be somewhat analogous to the thickened cortex and the narrowed medullary canal one finds in advanced cases of Paget's disease, associated with pain and which are relieved by operation.

DR ROBERT B OSOOD, Boston Dr Swett has called attention to the similarity of the phenomena he has studied to the sclerosing osteomyelitis reported by Garré in the *Beiträge zur Klinischen Chirurgie* in 1893 (Zehnter Band Zweiter Heft, pp 241-298). It will be remembered that in 1874 Poncet called attention to an observation of Ollier's of a periostitis with a clear exudate, albuminous in character, and without important signs of inflammation, to which the name "periostitis albumenosa" was applied. Cases of this nature have been reported from time to time. I remember encountering one over twenty five years ago which subsided without operative attack. This rather rare condition has been given different names,—"periostitis ex sudativa", "osteoperiostitis sereuse", "plastische periostitis". Volkmann considered the lesion to represent a "lymph abscess", though most observers have considered the morphological process to represent a subacute hematogenous osteomyelitis involving chiefly the periosteum. Garré reports four cases of sclerosing osteomyelitis from three of which cultures of either staphylococcus aureus or albus were recovered, but in some animal experiments these cultures proved innocuous when injected into the knee joint and the periosteal cavity evidently bacteria of low virulence. In no case of his was frank pus recovered from the lesions of the bone or from the sometimes accompanying joint effusions.

Garré suggests that the medullary occlusion may be of the nature of a central sequestrum and the microscopic findings of focal necrosis in the bone fragments in Dr Swett's cases would suggest this conception also. In Garré's cases lues was thought to have been excluded as a possible etiologic factor and although, I think Dr Swett does not mention it, I fancy that it was ruled out in all his cases. But it is well to remember that this mocking bird of all bone lesions yields to a nonoperative attack. It is perhaps significant that Dr Swett's first two patients had sustained their fractures from crushing rather than from leverage violence and that in his third case, although I believe no true fracture was ever discovered, a crushing injury had also been received which might well have severely wounded the periosteum. This is the tissue initially involved in the production of the lesions which have been so well described.

I am most glad of the opportunity to thank Dr. Sweet for his interesting and well planned discourse. A paper like this has real value which less thorough reports of supposed surgical curiosities often lack. The medico-legal importance of his findings is undoubted.

PRESIDENT JOHNSON The discussion from the floor is now open.

DR. LYMAN ALLEN Burlington Vermont This case may not be quite germane but the medico-legal aspects were similar.

A young woman was injured in a dynamite explosion, with frank osteomyelitis of the tibia but without fracture. After some eighteen months of pain and disability she had great relief when a piece of the cortex was removed leaving a slot perhaps half an inch wide and four inches long in the tibia. No fracture had existed.

The medullary cavity was not obliterated and there was no macroscopic evidence of osteomyelitis. The removal of this piece of bone and the opening of the slot relieved pain and enabled the patient to resume her occupation. I do not know whether the relief was permanent.

I have a feeling that the mere absence of a medullary canal alone probably does not cause the disability and that the alteration in weight-bearing while it may play a part is probably not necessarily a factor in the disability. Interference with venous and lymphatic circulation, the relief of tension by the opening of a slot and the alteration of the circulation in general probably furnish the answer to the relief of pain and therefore the curing of the disability.

PRESIDENT JOHNSON Is there any further discussion?

DR. F. J. COTTON Boston Mass. I would like to say Mr. President and gentlemen, that I am rather inclined to agree with Dr. Sever and Dr. Allen. We see so many fractures in which healing is accompanied by obliteration of the medullary cavity.

I think this is a very interesting group of cases and would like to emphasize what Dr. Allen just spoke of that is the classifications in which, with out fracture, trauma does lead to sclerosis of bone. There are a good many cases that we at one time classed as simple osteitis fibrosa noncystica, which never meant anything really definitely not parathyroid.

roid cases, localized affairs following a minor trauma.

There are certain specimens that we have been working over that show that this situation of a sclerosing osteitis without any infection we can discover but with small cysts perhaps only one is apparently originally of hemorrhagic origin. It seems perfectly possible that the bone may act to produce this sclerotic condition as a result of various stimuli. Certainly it reacts in that way in those cases in which you will dig out a lot of bone and find a pinhead infectious focus without previous osteomyelitis in which you can recover staphylococci. It apparently will react in the same way to localized hemorrhage.

I think whatever the cause is we get the same sclerosing thing which is talked of loosely as Garré's nonsuppurative osteomyelitis.

I think the pain in these cases is probably the sclerosis as such rather than the question of what has or has not happened to the medulla.

I believe this sclerosis can come from a number of original causes.

DR. CHARLES P. CHAMBER Montpelier Vermont. I would like to add a word about the case that Dr. Allen has spoken about, because the patient is not well. He saw the case I think about a year ago and advised that a section of the bone be removed.

The patient was comfortable a while, but continued to run a low grade temperature and a similar operation was done a few months later. Dr. Ober saw this patient last summer and advised removing the whole length of the top of the tibia between the two epiphyses. This was done and there were areas of sclerosis along the shaft but there was no definite pus found and the laboratory report was staphylococcus.

That operation was done about two months ago and the patient now is complaining of pain above the epiphysis. She still runs this low grade temperature. The wound is now practically healed. She has been a state case.

This injury originated from a dynamite explosion. The patient was living in a house about a mile from where the dynamite exploded. The windows blew in and she was quite severely cut. About six weeks after this injury she developed this infection in the tibia.

I think the case is somewhat similar to those Dr. Sweet mentioned but as Dr. Allen stated, I will have to agree with him she is a long way from being well yet.

DIABETES EPIDEMIOLOGY FROM DEATH RECORDS

BY ELLIOTT P. JOSLIN, M.D.* AND HERBERT L. LOMBARD, M.D.*

FACED with the problem of the inadequacy of death records in epidemiological studies, the authors have obtained an estimate of how closely the death records of Massachusetts approach the truth in ascertaining the epidemiology of diabetes. The items under discussion are age distribution, sex distribution, and duration increase, and incidence of disease. Diabetes is comparatively easy to diagnose and with the exception of priority of the other diseases listed in the "Manual of Joint Causes of

Death" the death records should portray the situation reasonably accurately. That this is not so is seen from the results of this study. Seven hundred and forty-four cases which later died and which previously had been diagnosed as diabetes by Joslin have been reviewed. The death certificates were signed by many different physicians as the majority of these patients died in their homes. The deaths occurred in two periods, 1926-28 and 1931-33 and the cases were so chosen as to be equal in number for both periods. No other method of selection was made.

The part of the series classified as diabetes on the death certificates represents about one

Joslin Elliott P.—Medical Director, George F. Baker Clinic, New England Deaconess Hospital, Lombard Herbert L.—Director, Division of Adult Hygiene, Massachusetts Department of Public Health. For records and addresses of authors see "This Week's Issue," page 22.

thirteenth of the total diabetic deaths in the State. While the sample is small, it is believed that it is representative of the State. The series represents a cross section of the diabetic population in respect to geographical location, economic status, and nationality, and while reviewed by Joslin represents the cases of many different physicians.

Table 1 shows both the composite picture for the six years and the same divided into two groups with a five-year interval.

Of the total number of individuals who had been diagnosed diabetes, only 62.9 per cent were so classified on the death records. An additional 13.0 per cent of patients had the

TABLE 3
CLASSIFICATION BY JOINT CAUSES OF DEATH OF PATIENTS WITH DIABETES WHO DID NOT HAVE DIABETES WRITTEN ON THE DEATH CERTIFICATES

	1926-28	1931-33
Cancer	22	28
Heart disease and coronary arteries	30	16
Pneumonia	3	5
Cerebral hemorrhage and embolism	10	6
Nephritis	13	3
Accidents	8	2
Others	18	15
Total	104	75

TABLE 1
CLASSIFICATION OF THE DEATHS OF 744 INDIVIDUALS WHO DIED WITH DIABETES

Group	1926-1928	1931-1933	Total
Diabetes cases	372	372	744
A—Classified as diabetes	60.0 ± 2.5%	65.9 ± 2.4%	62.9 ± 1.8%
B—Had the word "diabetes" on the death certificate but were otherwise classified	12.1 ± 1.7%	14.0 ± 1.8%	13.0 ± 1.2%
C—Failed to have the word "diabetes" on the death certificate. If they had, would have been classified as diabetes	17.7 ± 2.0%	9.1 ± 1.5%	13.4 ± 1.3%
D—Failed to have the word "diabetes" on the death certificate. If they had, would have been classified otherwise	10.2 ± 1.6%	11.0 ± 1.6%	10.6 ± 1.1%

word diabetes written on the certificate but due to Joint Causes of Death were classified otherwise. Twenty-four per cent of the cases did not have diabetes on the records at all, and about half of these (13.4 per cent of the cases) would have been classified as diabetes if the word had appeared on the death records. This indicates that the reported deaths in the State represent 82.5 per cent of the deaths that should be thus classified by the Joint Causes of Death, and 62.9 per cent of the individuals who had diabetes at time of death.

In the first period, 1926-28, 27.9 ± 2.3 per cent of the cases failed to have diabetes written on the death certificates, in the later period, 20.1 ± 2.1—a difference of 7.8 ± 3.1. This difference is significant statistically and indicates a slight improvement on the part of physicians in certifying deaths.

Table 2 shows the classification of cases with diabetes written on the death certificates, and Table 3 the classification of those without diabetes written on the death records.

TABLE 2

CLASSIFICATION BY JOINT CAUSES OF DEATH OF PATIENTS WITH DIABETES WHO HAD DIABETES WRITTEN ON THE DEATH CERTIFICATES

	1926-28	1931-33
Diabetes	223	245
Cancer	18	25
Tuberculosis	15	8
Accidents	2	4
Others	10	15
Total	268	297

The age distribution of the groups B, C, and D (table 1) did not differ from Group A. In this item alone, the death records portray the actual results.

The sex distribution differed materially in the cases without diabetes written on the death records from the classified cases. The sex ratio in the State and that in the classified series were practically identical, but was much higher in the cases without diabetes written on the records. This indicates that a larger percentage of men dying with diabetes, than women, are not so classified. This would tend to make one doubt the sex aspect of epidemiology of diabetes as portrayed by the death records.

TABLE 4
SEX RATIO IN THE 1926-28 SERIES

	Males per 100 Females
Sex ratio of diabetic deaths in State	58
Sex ratio of diabetic deaths in Joslin's series classified diabetes	57
Sex ratio of diabetic deaths in Joslin's series with diabetes not written on death records	76

Table 5 shows a comparison between the duration of the cases classified as diabetes on the death records and from Joslin's files. In both the earlier and later period Joslin's records give approximately one year longer duration of the disease than is obtained from the death records for the same cases. The average dura-

tion of total diabetic deaths in Massachusetts for 1930-32 is considerably less than for the sample. These findings indicate that duration of disease from the death records is not an adequate criterion

TABLE 5

AVERAGE DURATION IN YEARS OF DISEASE
PRIOR TO DEATH

	1926-28	1931-33	1930-3
Joslin's series from files	7.3	9.3	
Joslin's series from death records	6.4	8.0	
Total Massachusetts diabetic deaths			5.1

The application of rates found in table 1 would give an estimated number of deaths both from and with diabetes, assuming the sample to be representative and providing that none of the deaths so classified in the Massachusetts reports were from other causes. As all physicians are familiar with at least one test for sugar in the urine, it is probable that the only error of this type would be that of classifying an individual having sugar in his urine as being a diabetic without the confirmation of a blood sugar test. In a short series of eighty-three cases which were classified as either glycosuria or potential diabetes and which later died the death certificates recorded diabetes in 16.9 ± 4.1 per cent. In a series of 13,000 cases of suspected diabetes Joslin finds 13.5 ± 0.3 per cent not true diabetes and 2.5 ± 0.1 per cent with no definite diagnosis, a total of 16.0 ± 0.3 per cent. Using the standard deviation as a measure of variation for each of the rates used the resulting error in overstating the number

of diabetic deaths would lie between 3.6 and 6.2 per cent. Assuming this error to be 5 per cent and applying this classification rate of the State Registrar, the average yearly number of deaths with diabetes in Massachusetts in the period 1926-28 were 1385 and in 1931-33, 1690—an increase of 22.0 per cent. This is much less than the increase of 33.8 per cent between the reported deaths of 870 and 1164. This points to the probability that the increase in diabetes is less than would be expected from the death records, although the size of the sample prohibits a definite conclusion.

As a further check on the accuracy of the estimated number of cases dying with the disease in 1931-33 (1690) a comparison has been made between the number of cases alive, derived from this figure multiplied by Joslin's duration, and the number estimated by Bigelow and Lombard in "Cancer and Other Chronic Diseases in Massachusetts." The resulting figures are 15,700 and 15,000, respectively. This strengthens the opinion that the number estimated as dying with diabetes is approximately correct and gives additional weight to the previous estimate of the incidence of this disease.

From the study of 744 cases of diabetes it is concluded that the mortality from diabetes as recorded in the death records represents about four fifths of the true mortality as measured by the Joint Causes of Death and about two thirds of the mortality of individuals with this disease. The differences found in sex ratio, duration, and increase of disease warrant the assumption that epidemiological studies based solely on death records may be greatly misleading in portraying the true picture of diabetes.

THE GEORGE W. GAY LECTURE ON "MEDICAL ETHICS"

The Successful Doctor and the Human Side of Practice

BY JAMES D. HERRICK, M.D.

AN invitation to address medical students is often an incidental matter, a sort of by-product of one's presence in the university city while on a professional visit or while in attendance at a medical meeting. "Won't you say a word to the students?" casually remarks one friend of the faculty. "It makes no difference what you talk about. Even a few minutes will suffice. I'd just like to have the boys see you." That night during the wakeful hours in the Pullman one wonders whether the remarks that were made to the boys seemed as colorless and unsatisfactory to the students as to the speaker who for a few uncomfortable minutes felt that he was

on exhibition. The invitation to deliver the Gay Lecture, however, with notice several months in advance, with an assigned topic and that topic "Ethics" allowed a deliberate choice that pleased

gained in an extensive experience as practitioner, consultant, teacher and hospital physician.

In 1930 in presenting to Dr. Herrick the gold medal of the Association of American Physicians Dr. Kober termed him one of the most distinguished clinicians in the United States and always a painstaking student of clinical symptoms and most accurate in his description of observed facts.

In his monograph on coronary thrombosis Dr. Levine says of Dr. Herrick he "first finally focused the attention of the American medical profession on this disease. In 1911 he emphasized the fact that coronary thrombosis was a clinical entity could be recognized during life and that it need not and fatally. Under Dr. Herrick's aegis Fred Smith carried on the experimental work of ligating coronary vessels in the dog which is the foundation of our knowledge of the electrocardiographic evidences of coronary occlusion.

You, Dr. Herrick I present as our now universally recognized dean of clinicians, using the term not in its original sense of one set over ten but in the sense that all of us gladly acknowledge you as the leader among clinicians in this fair land of ours.

Herrick, James D.—Professor of Medicine Emeritus, Rush Medical College of the University of Chicago. For record and address of author see "This Week's Issue," page 32.

Delivered before the medical students of Harvard University November 7, 1935 under the endowment of Dr. George Washington Gay.

INTRODUCTION BY DR. HENRY A. CHRISTIAN
Of Dr. Herrick in 1924 when he had served as physician in chief, pro tempore at the Peter Bent Brigham Hospital. I wrote a delightful personality with matured clinical judgment no-

me I deeply appreciate the honor and am duly thankful

Dr Locke, as chairman of the Committee, wrote me that according to the Gay bequest the lecture was to deal with "medical ethics, economics, etc." I will not discuss medical economics for two reasons. In the first place the experience of the past six years leads me to question my qualifications. Secondly, there is available in the library the scholarly lecture of two years ago by Dr Osgood. This lecture contains such an excellent resumé of this topic that for me to take it up today would be needless repetition. My subject, therefore, narrows down to "medical ethics, etc." You may perhaps think I am talking mainly about "etc." for my theme is really the successful doctor. I trust, however, you may see that there is included something that bears directly on ethics and especially when I discuss as one of the qualifications of success an understanding of the human side of practice.

Success is the attainment of one's objective, reaching the goal. It is "getting there."

But objectives vary and standards are not uniform. No two of you have exactly the same aims. Perhaps some of you decided to become physicians by a process of exclusion. You did not know what else to do which is, I trust you notice, a little different from saying you did not know what else you were good for. Some hope to gain money, reputation, some aim to be teachers or medical writers, some are attracted by the lure of research or by curiosity concerning biologic science, particularly the mystery of disease, some think that the busy life of practice will bring them what they especially enjoy, close contact with men of all types and conditions, some are genuinely altruistic and are eager to help those who suffer from illness. Motives, then, are different, no two exactly alike.

Objectives also are not fixed, they are constantly changing. The altruist may in time become the self-seeker after wealth or reputation, the investigator is transformed into the practitioner, the well-to-do practitioner ends his days as a teacher or writer or as a charitably minded minister to the poor. These changes are by no means to be condemned for they may indicate progress and growth in mental and ethical development.

Let me cite two contrasting instances. An old acquaintance of mine had been sent to the United States by the church from an oriental country to be trained as a missionary doctor. Instead of returning to his native country he changed his mind and settled as a practitioner in one of our large cities. A year or so ago he came to consult me about his health. I asked him how he was getting on in practice. "Practice?" he said. "Why should I practice when

I can make more money at poker or playing the races?"

A schoolmate in a preparatory academy went as medical missionary to China, became physician to the Empress dowager and head of a large hospital in Peking. At about sixty-five, while on her sabbatical year in this country, she came to me for advice. Her Board of the Methodist Church had decided against her return because of evident cardiovascular disease. "I admit the existence of the disease," she said, "but I deny the wisdom of their decision. A letter from you stating that it will do me no more harm to work moderately in China than to live idly here will enable me to go back. Why should I not die helping the people I love instead of selfishly staying here in the vain hope that I may live a year or two longer?" I gave her the letter. She returned to China and for three happy years carried on her useful work, dying honored and revered by the people she had so faithfully and unselfishly served.

Need I point out the lesson? The first doctor was an ethical failure, a disgrace to the profession, the life of the second was one of which the profession may be proud, a true success.

It must be assumed that the doctor who is to be successful has a fair physical, mental and moral endowment, i.e., that he is in reasonably good health, is at least of average mental caliber and has a character that according to existing ethical standards is approved by one's fellows.

It must be admitted that some qualifications for success are outside one's control. All contestants start at scratch but they are not equally equipped. Heredity, environment, chance play a part. Some have by inheritance the qualities that go to make up a successful doctor. Some simply haven't the knack, just as some persons have no talent for music or mathematics. Environment and chance count. The young medical man thrown into association with studious, eager fellows catches their spirit and pushes ahead. Without this stimulating contact he may lag behind. Chance favors some, upsets the hopes of others. Disease, accident, financial reverses, unfortunate choice of location, family complications may be a hindrance to success, though, as is well known, what seems a misfortune is at times a blessing in disguise.

I have in my office desk photographs of the hands of a doctor from a western state—fingers twisted and deformed almost beyond belief by arthritis, metal rings to render more fixed some of the looser joints, corresponding changes known to be present in the feet. Yet in spite of this handicap the doctor was for years a successful, efficient general practitioner. When patients, lay or professional, complain unreasonably of their ill fortune in having arthritis or other retarding physical ailments, I some-

times show them this picture and tell the story Or I cite the case of Dr Robert H Babcock, who, though totally blind from the age of thirteen, became a successful practitioner, a teacher and writer, well known in the field of diseases of the chest. Or I remind them of Franklin D Roosevelt I am surely not straying from my topic in referring to such subjects Courage in adversity, and steady maintenance of the highest ideals are a part of nobility of character Character and ethics are near of kin

But admitting that success may depend in a measure on inborn physical and mental equipment, on luck or influence on an attractive personality, in the long run it depends first of all on hard work I have never known a physician who in the true sense was successful who was not a hard worker When Dr Frank Billings was studying intensively the question of focal infections, he put us all to shame as at sixty years of age day after day promptly at eight he appeared at the hospital where he carried on his investigations At the same time he was giving his clinics acting as dean of the medical school looking after a large private practice, and taking an active part in the meetings of many local and national bodies If you have not already done so read Osler's charming essay on "The Master Word in Medicine" The master key, he says, that unlocks the door leading to success is work Systematic and well planned work call it plugging if you will explains the success of a large proportion of successful medical men

Too much dawdling is bad To some English lords Lord Cromer of Egypt gave as a motto "Love your country, speak the truth, do not dawdle" Vainglorious doctors may resemble the chameleon who said he, "nearly busted" trying to change color as he walked from place to place on the Scoteluman's plaid Take time It has been said that the American's notion of progress is moving rapidly in the direction in which one is going The race is not always to the swift Speed is as often a sign of mania as of progress Fuss and pother and making motions do not always mean productive activity Remember Chaucer's Sergeant of Law,

"Nowher so bley a man as he there nas
And yet he semed blisier than he was"

To succeed you must know your subject, and this means study Study of textbooks certainly But even in your undergraduate days you should learn the supreme value of monographs original articles, current medical and other scientific journals Only in this way can you be trained in the ability to judge for yourselves the value of what is written, to distinguish fact from theory, hypothesis or the mere guess—and not a little that is in print is of this latter character 'To know by heart is simply not to know' "Let the boy examine and sift every

thing he reads, and take nothing on trust or authority," said Montaigne more than 300 years ago Yes, such ideas, though old, will stand repetition

So read the promising new, the approved classics of the past Read by cases, by subjects e.g., diseases of the blood or of the bone If attracted by any one subject, read exhaustively and ponder over it You will acquire in this way a sense of mastery You will learn the meaning of thoroughness A thin spread of knowledge of a great many things spells mediocrity The mediocre man is the dangerous man in the community He does not know the limitations of his own knowledge or those of others the risks of operation or of drug the healing power of nature Book knowledge is indispensable It means work and more work in the library And blessed result of it all, such work becomes your daily joy!

But you cannot be good practitioners unless you are constantly in touch with patients The bedside in the home or the hospital is the laboratory where, by experience you acquire knowledge and learn how to apply it By all means grasp at the chance to become connected with a dispensary or a hospital Generally only one with concentration of time and energy is better than two or three Welcome the opportunity or compulsion to teach No man is aware of what he knows or believes until he has tried to tell someone else about it or to write it down Join a medical society When you have something to say and only then, speak Take a medical journal Dr N S Davis, founder of the American Medical Association, in the third week of his practice, though poor, sent in his subscription to a journal

All this means that even with few patients the hours are being profitably spent There are so many who do not do this They are waiting for something to turn up, something to come their way There are many faultfinders envious of those who succeed They whisper of the use of influence, of luck, even graft The fault so often is not in their stars but in themselves that they are underlings They are idlers And one effect of all this study at the desk, in the laboratory and at the bedside is that it keeps you always a little ahead, always ready for more than you are now doing In this way promotion comes because it is deserved This was one of Pasteur's oft repeated sayings.

It is not enough, however, that you should "have the goods" You must be able to deliver the goods This is the art of medicine as contrasted with the science It means knowing how to apply your knowledge, more important, it involves knowing when to apply it Or to put it in another way, technique is not all of the art One of my colleagues, a leading otolaryngologist, has a telling way of expressing this truth He says he can in a few weeks teach a

graduate student how to perform a mastoid operation, it takes months to teach when to do the operation and when to refrain. Some doctors are honest, industrious, well-informed, even erudite, yet they fail. They lack good judgment and tact. Tact, as you know, means "touch." These men do not understand, and therefore do not get in touch with, human nature. They are not good salesmen, the other fellow who may not know so much gets their patients.

Guard against trying to acquire the art by too much conscious or unconscious imitation. Very properly you have your medical models, your heroes. In striving too zealously to follow their example you may become mere imitators, copying externals rather than fundamentals. The result is apt to be that you acquire only mannerisms. Be careful to avoid traits of even famous doctors when you are conscious that these traits are foreign to your nature and for you, therefore, non-assimilable, or that they are grounded in moral or intellectual weakness. Intellectual honesty and moral integrity are after all closely allied. Older men may teach you by informing as to facts, by inculcating lessons drawn from experience, by illustrating proper methods of thought, by stimulating you by wise advice but also—and of this your elders may be blissfully ignorant—by showing you by example how not to do it.

A word as to research. Real investigators are rare, i.e., those who can originate and independently carry on research. These men frequently make poor practitioners. Conversely, the practitioner is seldom a man of research in its highest sense. But the spirit of research is no monopoly of the laboratory of experimental physiology or pathology or biochemistry. It is, and should be found in the successful practitioner whether in the hospital or the home. He should have the curiosity that Lord Kelvin had when he so frequently exclaimed "Now, what's the go o' that?" Each case of disease is a problem for investigation. In trying to solve this problem of a case or a group of cases, the doctor may add to his own knowledge and perhaps to that of others. He has at least been stimulated to habits of more thoughtful and careful observation. To repeat, the spirit of research is the activating agent, the catalyzer of progressive and productive practice. It is a mistake to set up a real or a fancied barrier between research and practice. Many an investigator would do better work if he were not too fanatically wedded to the dogma of research for truth's sake alone and if he knew more of the problems of practice. Many a practitioner would be awakened to a new life if he were not wedded to the belief that experience, intuitive hunches, practical results were the all in all of medicine or if he were not so timid as to think he dare not enter the sanctum sanctorum reserved for research. Some of these features of

research and others that I have not touched upon may be found in Dr. Minot's excellent article on "Clinical Investigation" that appeared in the *Journal of the American Medical Association*, August 31, 1935.

Thus far I have tried to show that while success may depend in a measure on qualities that are inborn, on chance and environment, the main requirements are character, hard work, persistent study, daily contact with patients, all of which activities are permeated by the spirit of research. I wish now to take up another phase of the subject.

A physician's true success is estimated largely by what is commonly spoken of as service or what he does for others. This feature is inherent in the conception of medicine as a profession and not a trade. The distinction is not easily made for the legitimate income-earning and the professional factors overlap at many points. The physician is consulted for his opinion and not for wares that he sells from his shelf at a profit. He does not take orders, he issues them. The doctor, lawyer, priest, teacher, architect touch on something other than the material. They are motivated by the idealistic, artistic, altruistic, ethical. All this is implied by the term "profession."

The minister sees people at their best, the lawyer sees them at their worst, the doctor sees them just as they are. To no one more than to the physician is there offered the opportunity for service, to no one more than to him is the incentive to service more impelling. Rightly to embrace the opportunity to respond to the incentive the physician should possess a dual personality. He should be intellectually—or, as it is oftener expressed, scientifically—minded toward the disease but sympathetic or human toward the patient.

The training of the physician even in his premedical courses and as far back as to the secondary school leans toward the practical and scientific rather than toward the human attitude of mind, the attitude of emotion and sentiment. Geography is concerned more with the height or mineral content of the mountain than with the magnificence of the view when the peak is scaled. The imagery of Vergil and his portrayal of human motives are largely lost in stressing scansion and grammatical construction. History discusses the strategy of the campaign and the plan of the battle, but overlooks the suffering of the wounded and the desolation of homes. So, in his biologic study of the frog, the guinea pig and of man, the student continues to use the same yardstick that he used in solving his problem in the relatively dead or insensate mathematics, physics and chemistry.

In a measure this is necessary and as it should be. The practice of medicine is becoming more and more exact. The doctor who is oversympa-

thetic, i.e., in the derivational sense of the word "suffering with" his patient, may be lacking in the intellectual or unemotional qualities that are prerequisites of good judgment. This may be fatal to the patient's best interest. The scientific physician, on the contrary, may be callous to human suffering of mind as of body. This is wrong, is frequently harmful to health and is not necessary. In fact it is not so common as it is often thought to be, for most doctors are at heart sympathetic. Dr. John Brown in "Rab and His Friends" describes the loud laughter with which the students greeted the poor Scotch peasant woman who entered the clinic. The odd dress and strange manners of herself and husband were too much for them. But when they saw the hard cancerous breast, the courage with which without anesthetic the patient submitted to the operation, the tender devotion of the rustic husband and the courtesy and kindness of the surgeon,—none other than the renowned Syme,—tears coursed down their cheeks and as the brave little woman was wheeled away the amphitheatre rang with applause. I quote Dr. Brown's comments: "Don't think them (the students) heartless, they are neither better nor worse than you or I. They get over their professional horrors, and into their proper work and in their pity, as an emotion, ending in itself or at best in tears and a long drawn breath, lessens,—while pity as a motive, is quickened, and gains power and purpose. It is well for poor human nature that it is so. There is the lesson, pity as a motive."

We must all be on our guard lest enthusiasm over the strictly medical aspects of the illness leads us to forget the patient. "Doctor," a new patient said to me, "I do hope you will be different from the other doctors whom I have consulted. I trust you will look less at the x-ray picture and more at me." The busy attending man with his following of students and house staff was bustling down the ward to see the interesting case at the end of the row of beds. The Irishman in bed one leaned over to the Swede in bed two and said, "Ole, we ought to be a hell of a lot better. The professor has just walked by." There is a practical sermon on ethics in those two incidents.

You may not in your undergraduate days appreciate the force of what I am saying. It may be that the real meaning of the human side of practice will not come to you until as the family doctor you enter the home where with no intern, no attending man you must shoulder the full responsibility for the treatment of a serious illness. You are making your evening visit on the man with pneumonia. He is an interesting case. You record with care the physical signs, the blood count and the blood pressure. You are leaving the final directions for the night. The patient's breathing is rapid and labored, the delirium is marked. As he moans

with the pain of the cough you note the look of anguish on the face of the young wife who stands near with the two year old banging to her skirt. There are signs that another baby will come soon. Suddenly you sense it all. The loss of this husband, this father, this wage-earner means not only a broken heart. It means wrecked hopes, a shattered home, the wife the future wage-earner. You say, you scarcely know why. "This may be a critical night, I will stay." You have unconsciously transmuted your emotion into an act of service. The look of gratitude from the dim eye of the wife is your ample reward. You have learned something of the human side of practice. The patient is a case, to be sure but the case is a man.

In present day conditions of practice this feature is easily forgotten. There are fewer of the old type family doctors who though perhaps possessing less science, were often rich in the qualities that made them the family advisers, confidants and friends. There are fewer real homes and more apartments. Yet whether he is in his cramped apartment, his private room or ward in the hospital, he is the human being sensitive to pain, fearful of and not understanding illness, dreading death responsive to kindness and hurt by indifference or harshness. The doctor's dual personality must not be lost even though the family doctor is largely displaced by the hospital attending man.

Perhaps there is no call for me to discuss these topics before a class of Harvard students when your own teachers by precept and example keep this phase of medicine ever before you. And less reason for my so doing when there still pervades your class rooms laboratories, and wards the benign influence of that rare spirit, Francis Peabody who by act and word so perfectly exemplified the dual personality of the physician.

Every doctor aims to be honest. Yet one of the difficult things in practice is "to tell the truth." Patients consult us for our opinion and for advice as to treatment. Are they not entitled to the truth? Yes, but what is the truth concerning an illness? Suppose I say to a patient that he has tuberculosis or a leaky heart valve. I have told the truth as to diagnosis. But if the tuberculosis is curable if the valvular lesion is not inconsistent with length of years, in reality I may have uttered a falsehood. For tuberculosis may mean to the patient "quick consumption", and a leaky valve may be synonymous with sudden or dropsical death. My bald, naked truth is an untruth. You see what Emerson meant when he said "It is not the fact that imports, but the impression or the effect of the fact on the mind." Besides no one is infallible as to diagnosis or prognosis. The serious case may turn out better than I think

The supposed cancer may be an ulcer or diverticulitis, or it may melt away under iodide or arsenic. The patient is entitled to at least an explanation of what is implied by my diagnosis and to a modicum of hope that the illness may not be so serious as it seems to be or that modern treatment may help or cure. Lawrence Henderson, in discussing the problem of Physician and Patient as a Social System—and in a more penetrating and philosophical manner than I—expresses similar sentiments when he says "Do as little harm as possible, not only in treatment with drugs, or with the knife, but also in treatment with words."

We doctors too often forget that patients do not always grasp our meaning because we employ language they do not understand.

I could not convince a man of sixty-five that the trace of albumin in his urine was not of serious significance. On his report from the bureau of analysis was the finger, rubber-stamped in violet ink, pointing to the word *albumin*. This outweighed all my reassurances. One day I said "Why do you not worry about your wrinkles and your gray hair?" "Why, doctor," he said, "am I not entitled to have gray hair at sixty-five?" "You are," I replied, "and so you are to have a trace of albumin in the urine. Your trouble is simply gray hair in the kidney." I saw him no more for two years, when he again came to see me. "You don't remember the circumstances, doctor, but I was upset by your statement. I went to another doctor who promptly found Bright's disease. When he asked me what your diagnosis had been and I told him 'gray hair in the kidney', he was indignant and furious. He said he had never heard such a fool diagnosis in all his life. He had always thought Dr. Herrick, etc." *Haec fabula docet*. Beware of using figurative language in speaking to a patient who is literally minded.

The doctor, then, is to be human, sympathetic, helpful, always regarding the interests of the patient as paramount. This implies what is called character and a high standard of conduct or right thinking. Of such is the essence of ethics. So important is this in the conception of the best type of physician that there have prevailed even from the time of Hippocrates—with the well-known oath—to the present, rules of conduct often spoken of as codes of ethics. In order not to dictate in too arbitrary a manner the American Medical Association prescribes the principles of ethics rather than the code infringement of which may bring censure or more severe punishment to members of this national organization. These principles have to be modified from time to time to meet more explicitly the needs of changing conditions. Basically they are founded on the assumption that medicine is a profession not a trade, that a patient is a sufferer to whom the humane phy-

sician must offer help and that all physicians are members of a brotherhood, bound by mutual ties of friendship and helpfulness and not separated by barriers of enmity. Boiled down, the ethics of medicine is contained in the golden rule "Whatsoever ye would that men should do to you, do ye even so to them."

I shall not discuss in detail the various features of ethics. Dr. Osgood, Dr. Robey and others have well covered this ground in previous lectures that are in print. The puzzling question is often before the practitioner, What is proper under the circumstances? The answer may generally be found if he puts himself in the other's place. If he were the patient, what would he like to have done to him? If he were the other doctor, what treatment by his colleague would seem proper and friendly? An appeal to conscience is generally better than an appeal to the printed principles or to an official body of a medical society. Conscience will generally be found deciding in accordance with the printed precept.

Among features that deserve mention, some of them relatively trivial to be sure, are such things as avoidance of gossip, promptness in response to calls or at consultations, consideration for others' convenience, courtesy in converse, clearness and explicitness in giving directions, assumption of responsibility for risk in treatment or even for error of judgment instead of throwing the onus on the helpless patient or weaker colleague, the wickedness of getting the other man's patient by direct or indirect offensive advertising, or of injuring another's reputation by unjustified comment or innuendo. Much might be said, and it would be especially appropriate at the present time as to fees and the burden of the high cost of medical care. Secret splitting of fees is to be condemned. There should always be consideration of the patient's ability to pay. The pound of flesh attitude should be foreign to the doctor.

How shall I close this talk that has been, as I am acutely aware, not only informal but incomplete? Perhaps after having looked backward and having surveyed conditions of the present, I may appropriately venture to forecast the future. I do this optimistically. There are many *laudatores temporis acti* who are past the psalmist's three score years and ten, and others who are yet young, who are disheartened by the difficulties encountered in these last few years of storm and stress who believe that medicine has seen its brightest days and that the doctor of the future will be less successful, less honored, less useful than his predecessors and less high-minded. This gloomy view is unwarranted. As a science, medicine is far from exact or complete. There is still an enormous field for study. New facts and new principles await investigation in the laboratory and at the bedside. Cancer, many infections, endocrines

and scores of other problems await their Harveys, Pasteurs, Kochs or Theobald Smiths. The practice of medicine is still too empirical and crude. New instruments and new laboratory tests will make diagnosis more exact. Preventive medicine is still in its infancy. Dietetic and specific drug therapy will be more accurately and effectively applied. Psychology will be more sensibly and more successfully employed. Surgery will have triumphs as yet undreamed. Social and economic relations may radically change. The individualism of the practitioner may, for a time, seem to be lost in the group or in the imposed authority of the State. But whatever the status of medical science, or the imposed obligations of Society from out this unknown future there will surely emerge, as long as disease exists, two figures,

the physician and the patient constituting the social system of Henderson. Then as now this doctor must maintain most intimate relations to his patient. Then as now there must be heard the words "my doctor", "my patient". This doctor, if successful in the true sense, must possess the dual personality, he must be scientific and human or humane. He must know his facts and the principles underlying them, and have the ability to apply them in treating the sick. In addition he must have that touch of nature that makes the whole world kin and that enables him to see in the sufferer from disease a man and brother. In a word he must, and I believe will, be a man of character, which means a man of right living. And thus, as I understand it, is ethics.

THE DEATH RATE FROM ALCOHOLISM

BY TIMOTHY LEARY, M.D.*

THE accompanying chart illustrates graphically a situation with reference to alcoholism which has become a serious menace. This chart records the deaths in which alcohol has been an important agency coming under my observation as Medical Examiner of Suffolk County. Most of the deaths have been directly due to alcoholism as such. The added cases include a percentage of alcoholic pneumonias in which the alcoholic factor was of primary importance, a percentage of cases of fractured skull in which the degree of alcoholism was extreme and was responsible for the violence, as from a fall, which led to the fracture. The list does not include deaths from automobile accidents since in doubtful cases it was difficult or impossible to differentiate the influence of the alcohol and that due to the traumatism. The criteria as to what should be listed under alcoholism have not changed to any measurable degree during the period recorded.

There are many types of observation which can serve as bases for judgment on the extent of the alcoholism in a population. The records of arrests for alcoholism and the hospital admissions for this cause are valuable, but in the final analysis the number of deaths arising out of alcoholic intoxication furnishes perhaps the best barometer of alcoholic overindulgence.

As seen by the chart the deaths related to alcoholism in this service were on a relatively standard average basis in the years 1913, 1914 and 1915. The years, 1916 and 1917, were those of prosperity, the silk shirt period when war loans had financed production and workers were well paid. In 1918 and 1919 we were preparing to and had entered the war. It was no longer fashionable to get drunk and the men who drank had difficulty in getting or

holding jobs. Under the influence of a patriotic urge we became one of the most temperate people in the world. Then came prohibition. In 1920 no liquor was available. The stocked liquor was shortly used up and new sources of

*Leary Timothy—Medical Examiner, Suffolk County. For record and address of author see "This Week's Issue," page 3.

supply were not as yet organized. In 1921 and 1922 deaths for a considerable part were in individuals who had resource to bathing alcohol, extracts—jamaica ginger, vanilla—perfumes and bay rum. By 1923 the bootlegging business was well established and sources of supply were many. The eleven years from 1923 to 1933 inclusive mark the period of activity in bootleg products. Smuggling of concentrated alcohols was no more difficult and was more remunerative than the smuggling of beer and wines. The illicit distillation of alcohol flourished. We developed in the public a taste for beverages with a kick which could only be satisfied by concentrated alcohol. It will be noted that there is a more or less progressive downward trend in the death rate during these years. We were gradually settling down toward a standardized but relatively high death rate.

Prohibition was abolished Dec 4, 1933. In the State of Massachusetts the local alcohol control system permitted the sale over the counter by druggists of 95 per cent alcohol (190 proof). This is in contrast to the practice elsewhere. In New York State, for example, a physician's prescription is necessary for the purchase of ethyl alcohol. The usual drug store price for ethyl alcohol is eight ounces for a half dollar. During

the year ending Dec 4, 1934, there was a tremendous rise in the death rate. This, in my opinion, based upon evidence of what the decedents had been drinking, was due in very large part to the drinking of ethyl alcohol. Diluted properly perhaps at the beginning of a drinking bout, the fluid came to be drunk with less and less attention to dilution until delirium or unconsciousness supervened and treatment was of little or no avail. It requires but 0.6 per cent of ethyl alcohol in blood and brain to bring about a fatal issue. Quantity and concentration are both factors of importance. The human body can oxidize about 10 cc of ethyl alcohol per hour. The absorption of alcohol in these cases takes place more rapidly than oxidation can destroy it. The accumulation of the drug within the tissues gives rise to dangerous percentages often before the victim succumbs to sleep or delirium.

The increased death rate in this district following the abolition of prohibition is in contrast to the lowered mortality reported elsewhere throughout the country, notably from New York City. It is a reasonable conclusion that the readiness with which ethyl alcohol can be purchased over the counter in drug stores in this state is a factor in this local increase.

FURTHER EXPERIENCE WITH THE FRACTIONAL 'PHTHALEIN TEST

BY EARLE M. CHAPMAN, M.D.*

KIDNEY function tests that require the prolonged cooperation of the patient with regard to diet and fluid balance or the expense of chemical analyses do not conveniently serve the purpose of estimating kidney function in routine practice. Our continued use of the fractional phthalein method of estimating kidney function leads us to believe that it is both practical and reliable. In 1933 Chapman and Halsted¹ described the use of this test in forty-three cases including hemorrhagic arteriosclerotic and degenerative Bright's disease.

Four years of experience with this test have established it as a routine procedure in the wards and in the out-patient department of the Massachusetts General Hospital. The technique is simple. The patient empties the bladder, drinks two glasses of water and one half hour later 10 cc (6 mg) of phenolsulphonephthalein is given intravenously. In a normally hydrated person voided specimens of urine are then easily obtained fifteen and thirty minutes after giving the dye. The whole test occupies one hour and the results can be read immediately with the standard colorimeter (Hynson, Westcott and Dunning). The one and two hour specimens are no longer obtained as we have shown that the curve of dye elimination with

a high initial output (normal minimum 25 per cent) is the significant feature of 'phthalein excretion. One third of the forty-three patients with Bright's disease had a total dye output of 55 per cent or more by the old method of hourly collections yet in each there was a delay in the dye excretion shown only by the fractional method. This delay, reflected chiefly in the fifteen minute output, indicated an impaired kidney function.

Our further experience is recorded here for convenience in figures representing the curve of dye excretion in normal persons and in patients with acute and chronic hemorrhagic Bright's disease. As this is the most common type of Bright's disease it alone is used for illustrative purposes.

Chart 1 shows the average curves of normal dye excretion, the line A-B representing forty tests on twenty normal individuals. A Duboseq colorimeter was used. The line C-D represents the average of twenty-six tests on twenty-six ward patients without renal disease done routinely by interns using the standard colorimeter. It is evident that the latter method is sufficiently in agreement with the more accurate colorimetric determinations to permit its use as a reliable test of kidney function. Fluid intake¹ or anemia² does not alter the dye excretion.

*Chapman, Earle M.—Member of Staff, Massachusetts General Hospital. For record and address of author see *This Week's Issue* page 32.

Chart 2 represents the course of acute hemorrhagic Bright's disease in a fourteen year old boy. He was very ill with sudden hematuria and edema and had hypotensive encephalopathy (convulsions) at the onset of his illness. He improved slowly and then after the tonsils were removed the improvement was rapid. He is now in the latent stage, having only a very slight trace of albumin in the urine. Here the fractional 'phthalein test reflects the diminu-

CHART 1

ished function that occurs in acute hemorrhagic disease and coincident with clinical recovery we see that the 'phthalein output has returned to normal. This case is illustrative of

CHART 2.

the eight additional cases of acute disease we have observed in the past two years. However four of these showed a return of kidney function only to subnormal levels as they entered the chronic active stage of the disease.

Chart 3 shows the average curve of dye excre-

tion of thirty-one patients who entered the hospital with chronic active hemorrhagic Bright's disease not in the terminal stage. We believe that this test is of particular value in estimating the kidney function of patients with progressive Bright's disease. The increasing damage to the functioning tissue is shown chiefly by a decrease in the fifteen minute output of dye. By the usual hourly method MacKay³ states that

the 'phthalein test may be normal until at least half of the functioning tissue has been destroyed. Chart 4 shows the course of a patient with

CHART 4

progressive kidney disease. This was a sixteen year old girl who first entered the hospital with the acute disease and progressed through the chronic active stage to the terminal event in uremia. Necropsy eight months after the last recorded test showed that she had diffuse glomerular nephritis. Here we see the progressive decline in kidney function over a period of two years reflected mainly in the fifteen minute dye output. It was not until six months after the last test that uremic symptoms appeared.

From this and similar cases we have attempted to govern prognosis. It would be hazardous to offer a graded prognosis on the basis of this test alone but we have followed seventeen patients with progressive Bright's disease who lived an average of six months after they could excrete less than 5 per cent of dye at the fifteen minute interval. Clinically some of these patients seemed surprisingly well but none lived over twelve months with this degree of kidney damage.

Like other clinical tests of body function a single fractional 'phthalein test is not to be accepted as proof of impaired renal function unless it forms a part of the clinical picture. Particularly in congestive heart failure with a

the ordinate. Excepting those tests marked with a cross the two methods compare favorably. (See upper left and lower right sections of chart 5.) In five instances (upper left square) the fractional 'phthalein test alone indicated impaired kidney function.

CONCLUSIONS

The fractional 'phthalein test is a practical and reliable method of estimating kidney function. It reflects the changing function of the kidneys in acute hemorrhagic Bright's disease and the progressive decline in function in the chronic active stage. Its possible prognostic value has been indicated and its limitations discussed.

CHART 5

diminished blood flow through the kidneys the 'phthalein excretion is so delayed as to be of little value in estimating renal function. The reverse of this has been observed in cirrhosis where the 'phthalein output may be unusually high because of the inability of the damaged liver to excrete the usual 15-20 per cent of the dye. In the nephrotic stage of Bright's disease the dye output may be normal until late in the course of the illness. During this same period we have observed that other tests of function have also failed to indicate kidney damage. The explanation for this is not clear.

To estimate the accuracy of the fractional 'phthalein test we have done comparative tests of urea clearance* on thirty-eight individuals with varying amounts of renal damage. Chart 5 shows these comparative tests. The 'phthalein test is charted against the abscissa, the per cent of dye excreted in fifteen minutes, while the standard urea clearance expressed in per cent of average normal function is plotted against

THE TEACHING OF GYNECOLOGY AT THE
NEW ENGLAND MEDICAL CENTER

BY LOUIS E. PHANEUF, M.D.*

THE Boston Dispensary, established in 1796 has always maintained large out-patient clinics where teaching has been conducted for a great many years. In 1929 the Tufts College Medical School, the Boston Dispensary and the Floating Hospital combined to form the New England Medical Center and at that time the gynecological clinic was organized for the purpose of teaching Tufts medical students. During the past year, 1934, the total number of women treated in the gynecological clinic was 2209 and the total number of visits was 8928. It is felt at Tufts College Medical School that the teaching of gynecology to the third year class should consist largely of the examination of patients and the carrying out of clinic or office procedures. It is further felt that except for seeing living pathology the third year students get very little out of witnessing involved pelvic operations, because on the one hand, this form of teaching is too far advanced for them, and on the other hand, operations performed deeply in the pelvis are difficult for them to see. A vote recently taken at the Tufts College Medical School shows that the undergraduates favor out-patient work. During the fourth year an elective course in gynecology is available. One member of the class is assigned for a month to the general clinic at the New England Medical Center, where he works as a regular assistant under supervision.

In order to utilize the large amount of material available, the floor plan has been designed according to the following drawings furnished by the architect.

The daily teaching clinics are carried on as follows:

The patient enters the consultation room where the history is obtained by the instructor, she then enters the examining room and is draped. In the meantime the history is discussed with the members of the section. The next step is the examination, first by the instructor and then by the students. After the examination the necessary advice and treatment are given. The group then adjourns to the conference room where further discussion of the case takes place with the idea of clarifying anything that may be vague.

While the teaching is going on other members of the gynecological staff treat the patients in the general clinic, and lesions of unusual interest are demonstrated to the student group. The teaching does not in any way interfere with the progress of the general clinic, which is a unit apart from the teaching suite as shown by the drawings.

A large number of patients, representing a wide variety of gynecological conditions are

Phaneuf, Louis E., Professor of Gynecology, Tufts College Medical School. For record and address of author see "This Week's Issue" page 22.

seen during a forenoon. The normal conditions are readily compared with the abnormal and the student has the opportunity of applying the knowledge gained from his lectures at the medical school in the discussion of the diagnosis, differential diagnosis and treatment of each individual case.

First hand experience and individual instruction are obtained by the students, there being three, or occasionally four, assigned to one in-

tory, examination and laboratory findings. The diagnosis, differential diagnosis and treatment are purposely omitted and are brought out in the discussion.

Large fibroid tumors or ovarian cysts are marked out on the abdomen with a skin crayon and may be readily demonstrated to the class. With the patient properly draped, and her eyes covered with a towel, a proctentia may be shown without embarrassment to her. Large

structor. The common variety and the rarer gynecological lesions are simultaneously encountered, emphasis being placed upon the more common lesions which these undergraduates will more frequently meet in their later private practice.

Clinical lectures have been given for the past three years. These are held in the latter part of the second semester, once a week for eight weeks, during which time eight important subjects in gynecology are discussed, with the presentation of patients. Each member of the class receives a mimeographed copy of the his-

story, examination and laboratory findings. The diagnosis, differential diagnosis and treatment are purposely omitted and are brought out in the discussion. Large fibroid tumors or ovarian cysts may be seen, together with similar conditions which have been repaired by plastic operations, thereby demonstrating the "before" and "after", and the general condition of patients who have been treated for malignancy, either surgically or by irradiation may be brought to the attention of those present.

This form of teaching in our hands has proved to be very satisfactory.

I wish to thank Mr. Frank E. Wing, Superintendent of the Boston Dispensary, and the architects, Andrews, Jones, Biscoe and Whitmore, for their cooperation in furnishing the architects' drawings.

ELIMINATION OF POSTOPERATIVE PAIN FOLLOWING HEMORRHOIDECTOMY

BY NATHANIEL J. SIMMONS, M.D.*

THE general practitioner is confronted with a few conditions that cause more acute suffering than prolapsed hemorrhoids. The palliative treatment of this anorectal condition by means of suppositories or salves is of no avail in cases where the disease process has resulted in organized tumor formation. The injection treatment has been of inestimable value for moderate sized bleeding and protruding varicose and capillary internal piles but should never be employed when hemorrhoids are large and hypertrophied, acutely inflamed, strangulated, extensively ulcerated, or when the patient suffers from complicating rectal diseases. There-

fore a large percentage of hemorrhoids must be operated upon if the patient is to be relieved.

Many individuals fear a hemorrhoidectomy because of the postoperative pain. Their fears are not unfounded. The pain following this proctological procedure is caused by the sphincter muscles contracting down on the fresh wound, the irritating discharge, the pressure pain against the sphincter muscles on the first evacuation of the bowels, the possible necessity of catheterization or a combination of several of these factors. The surgeon's duty is to eliminate so far as possible these conditions.

The problem which confronts the proctologist is to find a local anesthetic that will render rectal surgery painless or practically so for

*Simmons, Nathaniel J.—Assistant Surgeon, Out Patient Department, Beth Israel Hospital. For record and address of author see "This Week's Issue" page 32.

several days following the operation. If we can assure the patient that the postoperative pain can be mitigated, then rectal surgery will be one of the operative procedures which will not be unnecessarily postponed.

A good local anesthetic must first of all possess a specific affinity for nerve tissue and be retained at the site of injection long enough to perform the operation. The analgesic agent must paralyze the nerve tissue at a low concentration without poisoning the other tissues and the change brought about in the sensory nerve must cease after a certain time without leaving any aftereffects. It must be taken up by the circulation in a detoxified state. When the anesthetic solution is injected, it must not irritate or cause pain, which is also one of the requirements after its action has ceased. It is also important that the solution does not decompose during sterilization.

Various local anesthetic solutions were experimented with in an effort to obtain the desired fulfillment of a painless postoperative convalescence. The injection of novocaine in one per cent solution does not produce this result, although it produces local anesthesia at the time of the operation. Quinine-urea hydrochloride in 3 per cent solution is tremendously painful on and after the injection and the anesthesia lasts only a day or two. A solution of nupercaine (percaine) in 1/1000 dilution is only effective two to three hours. The analgesic solution made of anesthesin 3 per cent, benzyl alcohol 5 per cent, ether 5 per cent, and olive oil 82 per cent gives prolonged anesthesia but was discarded because the injections are extremely painful to the patient and because of objectionable taste in the mouth.

Wheeler¹ used a solution of Benacol (a mixture of five parts each of para amino benzoyl ethyl anil benzoate and phenethylol in ninety parts of rectified oil) which he claimed desensitizes the operative area from three to five days. Gorsch² used the same solution to which he added bntesin (bntyl para amino benzoate) and a basic procaine, with similar results. A solution containing anucaine, benzyl alcohol, and almond oil which works equally well has also been reported by Gorsch. Best³ does not infiltrate the sphincter muscles with a local anesthetic, preferring to operate under sacral or spinal anesthesia. Postoperative pain was relieved by him in one hundred cases by introducing in the rectum and on the dressing an ointment consisting of three ounces of one and one half per cent carbolyzed vaselino and one ounce of one per cent nupercaino ointment. Rosser⁴ and Hertzler⁵ found that Diethane (piperidinopropyl di phenyl urethane hydrochloride), a comparatively new anesthetic, produces an anesthesia lasting from six hours to four days. Frankfeldt⁶ reported that he has obtained an anesthesia in hemorrhoidectomies for four or

five days using a one per cent solution of novocaine followed by an injection of 3 cc. of nupercaine in oil solution into the sphincter muscles.

The most satisfactory local anesthetic in hemorrhoidectomies seems to be nupercaine in oil. The formula is as follows: Nupercaine "Ciba" base 0.5 per cent, phenol 1 per cent, benzyl alcohol 10 per cent, and oil of sweet almond. This solution was made up at the suggestion of Gabriel⁷ for the treatment of fissure-in-ano. It has been used by Simmons⁸ for pruritus ani. This anesthetic produces prolonged anesthesia of the sphincter muscles, causes only slight pain, if any, on injection, gives complete relaxation, and is not toxic in the amounts which have been used. The anesthesia lasts from seven to ten days. The prolongation of anesthesia and nontoxicity is due to the slow absorption of the oil. This solution was used in thirty hemorrhoidectomies, with no postoperative pain in twenty six and only minimal discomfort in four cases. Contraindications to its use are local infection and eczema or possibly an idiosyncrasy to the drug, which have not been encountered in any of these cases.

The operation may be performed at the office if there is only one hemorrhoid but it is better to hospitalize the patient on account of possible postoperative hemorrhage. The preoperative directions and technique are as follows: A soap suds enema is given the night before the operation, 8 grains of sodium pentobarbital are given two hours before the operation and supplemented by a hypodermic of one quarter grain of morphine sulphate and 1/200 grain of scopolamine an hour later. This allays any fear and excitement that the patient may experience.

The patient is placed in the lithotomy position as the separation of the legs automatically retracts the buttocks and gives excellent exposure. The anal region is shaved, scrubbed with soap and water, and an antiseptic applied. About 10 cc. of a one per cent solution of procaine hydrochloride is injected subcutaneously around the anal canal, and then five to ten cubic centimeters of the nupercaine solution in oil is warmed slightly and drawn up into the syringe fitted with a twenty five gauge needle one and one half inches in length. Three to five centimeters of this solution are injected at the posterior commissure into the posterior and posterior lateral fibers of the external sphincter muscles. The same amount is used anteriorly into the anterior and anterior lateral fibers. Anesthesia is obtained almost immediately and the operation may be begun as there is complete relaxation of the sphincter muscles. The anal skin is now retracted on either side with Allis forceps and the internal hemorrhoids are pulled out of the rectum to be grasped by Pennington forceps. The following is the technique employed: the hemorrhoids and hemorrhoidal feeding veins are dissected from their attach

ments for one-half inch or more depending on the size of the hemorrhoids. Great care should be exercised to prevent injury to the sphincter muscles. Chromic catgut No 1 or woven silk is placed beneath the pedicle, and the entire pile with relaxed mucosa is drawn down and outwards as far as possible. It is then ligated and excised. Enough stump is left to prevent slipping of the ligature. Skin tabs and external hemorrhoids if present are removed at the same operation. It may be necessary to inject one-half cubic centimeter of the anesthetic solution under a skin tab before removal.

A pressure pad is applied to the anus and the patient in a very comfortable state is returned to his room. Liquid diet is prescribed exclusively for two days to prevent cramps or desire to defecate.

Sitz baths are advised twice daily to promote healing. Mineral oil is given morning and night beginning with the third day postoperatively, and the patient is urged to defecate on the fourth day, or four ounces of mineral oil are instilled into the rectum followed in two hours by a soapsuds enema. The patient may be discharged from the hospital on the fifth day.

In the description of the operation it will be noted that the sphincter muscles were not manually dilated. The reasons for not dilating them are as follows: (1) Relaxation over a prolonged period of time is not obtained, (2) the tearing of the muscle fibers results in a fibrosis with possible loss of sphincter tone, (3) infection and rectal hematomas may occur due to excessive trauma.

Precautions which should be borne in mind

when injecting this local anesthetic are as follows: (1) The finger should be inserted into the anal canal to guide the direction of the needle and avoid penetration of the rectal mucous membrane which might cause infection, (2) the oily solution should not be pooled as it may lead to a rather painful induration, (3) any intradermal injection may lead to a slough.

By the use of the above technique and the local anesthetic which has been described, I believe that postoperative pain can be avoided in the average individual.

SUMMARY

In thirty cases of hemorrhoidectomies prolonged anesthesia and relaxation of the sphincter muscles were produced by the use of the local anesthetic nupercaine in oil (Ciba). The convalescence following this local anesthetic is practically painless. The requirements of a good local anesthetic are reviewed briefly. A simple technique for performing a hemorrhoidectomy is described.

AMERICAN ACADEMY OF TROPICAL MEDICINE

At the meeting of the American Academy of Tropical Medicine in St. Louis on November 20 and 21, the following officers were elected: Dr. Richard P. Strong, of the Harvard Medical School, president; Dr. Wilbur A. Sawyer, director of the International Health Board of the Rockefeller Foundation, vice-president; Dr. Ernest Carroll Faust, of the Tulane University School of Medicine, secretary; Dr. W. W. Cort, of the School of Hygiene and Public Health, the Johns Hopkins University, was reelected treasurer; Dr. William H. Taliaferro, of the University of Chicago, and Dr. Thomas T. Mackie, of the School of Medicine of Cornell University, were elected members of the council. Initiated by the academy, the American Foundation for Tropical Medicine held its organization meeting, electing as president Dr. Isaiah Bowman, president of the Johns Hopkins University, and as executive secretary Dr. Earl B. McKinley, dean of the School of Medicine of the George Washington University. The foundation will be incorporated in the District of Columbia and will

hold its next meeting late in January when a formal program will be adopted for 1936.—*Science*

CASE 22011

PRESENTATION OF CASE

First Admission A four year old white American boy was admitted complaining of difficulty in breathing.

Since the age of two years the child had frequent spontaneous attacks of difficulty in breathing associated with wheezing respiration and cough, the character of which was not recorded. These attacks recurred every two or three weeks each one lasting for about one or two days. There was no associated fever or emesis.

Physical examination showed a well developed and nourished boy who appeared to be comfortable. Except for the presence of harsh breathing throughout both lungs the examination was said to be negative.

The patient was skin tested and found to be sensitive to feathers, horse dander and egg. He was discharged on the eighth day.

A month later an x ray taken in the Out Patient Department showed increased density of the shadows of the lung roots. The lung fields were clear. He received a series of five x ray treatments to the chest with no symptomatic change. Persistent attempts at desensitization were made. Another x ray taken one year after the first exhibited the same increase in hilar markings as well as a decrease of radiance at the left apex. The attacks of asthma continued to occur at frequent intervals there after.

Second Admission, nine years later, at the age of thirteen.

For the past few years he had been having asthmatic attacks associated with cough at intervals of two to fourteen days. There was no cyanosis. No note was made of the presence of expectoration. Each episode lasted for about two or three minutes occurred suddenly with out relation to activity and subsided either spontaneously or after inhalation of fumes of burning powder. There were about three such spells a day during the attacks but in the interval between attacks he felt quite well. Two weeks before admission he developed malaise, chilly sensations, and fever. Thereafter he felt fairly well but continued to have an evening rise of temperature to 101° or 102°. He had

no night sweats, ready fatigue or hemoptysis. There was no cough except during the attacks.

Physical examination showed a poorly developed and nourished thirteen year old boy. The larynx and sinuses were negative. There was slight scoliosis to the right in the lumbar region. The patient was pigeon breasted and had a barrel shaped chest. There was slight impairment of resonance at both apices anteriorly and posteriorly. A moderate number of squeaks, wheezes, and musical rales were heard in the right chest. Expiration was not markedly prolonged. The heart was negative. The blood pressure was 100/40.

The temperature was 100°, the pulse 130. The respirations were 30.

Examination of the urine was negative. The blood showed a red cell count of 4,650,000, with a hemoglobin of 80 per cent. The white cell count was 22,000, 84 per cent polymorphonuclears. There were no eosinophils. Repeated examinations of the sputum were negative for tubercle bacilli. The stools were negative.

X ray examination showed considerable increase in the density and size of the abnormal area in the lung roots. The dense area was mottled and extended from the hilus well beyond the midchest bilaterally. The heart shadow was negative.

The patient had a rather croupy expiratory cough which became productive of thick mucopurulent material with subsequent treatment. The temperature exhibited daily fluctuations reaching 102° and 105° in the evening until the end of the second week, when it began to subside. Thereafter it remained between 98° and 100°. The severity of the cough and attacks of asthma lessened and he was discharged on the twenty third day.

Third Admission, eight years later, at twenty one years of age.

The patient had been treated at the Out Patient Department for a year after his last discharge and then, being somewhat improved, he did not return for six years. During this interval he had infrequent attacks of asthma but shortly before his return he began to have paroxysmal morning cough. Wheezing respiration became fairly constant but was of slight severity. He suffered from no acute attacks at this time. He was treated at the clinic for about a year with little change. There was no evident relationship to season or contact nor had there been any previously. Two days before entry he developed a tickling sensation in his throat and on the following day had several shaking chills, after each of which he felt feverish. There was no exacerbation of his previously existing symptoms.

Physical examination showed a poorly nourished patient with slightly labored and somewhat noisy breathing. There was slight cyanosis of the acral parts. The throat was injected and there was considerable postnasal mucoid

discharge As a result of the scoliosis previously noted there was increased prominence of the left chest posteriorly. The heart was rapid but otherwise negative. The blood pressure was 110/70. The lungs showed normal resonance. There was prolonged expiration, and at the left base posteriorly a slight exaggeration of the breath sounds. Many inspiratory and expiratory musical râles and a few scattered coarse moist râles were audible generally.

The temperature was 103°, the pulse 110. The respirations were 25.

Examination of the blood showed a white cell count of 12,000, 82 per cent polymorphonuclears, 14 lymphocytes and 4 eosinophils. The sputum consisted of mucoid material and repeated examinations for tubercle bacilli were negative. The sedimentation rate was 121 millimeters per minute.

X-ray examination showed that the previously observed lesion had spread to involve both upper lobes. There were some changes in the left lower lobe as well.

Following symptomatic treatment the temperature and pulse returned to normal on the fifth day and there was improvement in the patient's general condition. He was discharged on the tenth day.

Final Admission one month later

Following his last discharge the patient was troubled with a severe racking morning cough which lasted for about half an hour and was productive of large amounts of foamy watery material occasionally thick and mucoid in character. There was no blood present. He felt well at the end of two weeks, but shortly thereafter he became nauseated and vomited twice. He remained in bed for ten days preceding his final admission and his cough became more frequent. His pulse became quite rapid and his temperature often rose to 103°. He felt quite weak but there were no other complaints.

Physical examination showed a sick looking young man sitting up in bed with slightly labored breathing. There was moderate cyanosis but no clubbing of the fingers. The skin was hot and moist. The throat was red and there was a marked mucopurulent postnasal discharge. Chest expansion was forced and there was bulging of the interspaces with expiration. There was dullness over the left chest at the level of the angle of the scapula. The lungs were full of asthmatic wheezes, but no fine râles were audible. The heart was very rapid and there was marked gallop rhythm best heard at the apex. There were no murmurs. The blood pressure was 120/80.

The temperature was 102.6°, the pulse 144. The respirations were 32.

Examination of the urine showed a slight trace of albumin but was otherwise negative. The blood showed a red cell count of 4,000,000, with a hemoglobin of 70 per cent. The white cell count was 23,000, 88 per cent polymorphonuclears. The sputa were mucopurulent and

no tubercle bacilli were found. The nonprotein nitrogen of the blood was 27. Intracutaneous injections of 1:20,000 old tuberculin showed a negative reaction in forty-eight hours. An electrocardiogram showed a slight inversion of T₁, prominent P₂ and P₃, and a diphasic Q-R-S. There was right axis deviation.

X-ray examination of the chest showed no change from that previously described.

The temperature remained elevated and at the end of the first week it rose to 105°. The throat and tonsils remained inflamed and a slight nonfluctuant bulge appeared on the right side of the pharynx. Respirations were markedly asthmatic and the patient remained cyanotic. Increasing cyanosis was relieved temporarily by an oxygen tent, but the patient failed rapidly and died on the eighth hospital day, sixteen and a half years after the first admission.

DIFFERENTIAL DIAGNOSIS

DR DONALD KING I do not know just why the x-ray treatments were given. In a child of this age with dyspnea an enlarged thymus may have been considered. I do not believe that treatment was given for enlarged hilum glands. I am inclined to assume that at the time of this patient's first admission x-ray treatment was being tried out as a form of treatment of asthma.

At the time of the second admission it is of interest to note that the record says that the musical râles were limited to the right side. It is conceivable that there was at this time localized pressure on the right bronchus from an enlarged gland, but I am assuming that this was a case of bronchial asthma with a bilateral and not a "unilateral wheeze."

At the first admission skin tests were found to be positive, but we are led to believe that these tests did not help in treatment.

The history then is that of a boy who was followed from the age of four to his death at the age of twenty-one. He first came in with what seems to be typical bronchial asthma of two years' duration. There is no evidence of enlarged thymus or inhaled foreign body or enlarged glands pressing on the bronchi. Skin tests showed the patient to be allergic.

He comes back to the hospital at the age of thirteen. He had had fairly severe asthma during the interim and now has a definite barrel chest and pigeon breast deformity. He is brought in because of an acute respiratory infection, with fever, purulent sputum, and an increased white count with a high percentage of polymorphonuclears. Eight years later at the age of twenty-one he comes back again. During six of these eight years he has been comparatively free from asthma. He now returns with an acute infection of the upper respiratory tract as shown by the redness of the throat and the marked postnasal discharge. There were chills at the onset and without much question there was also a fever.

lower respiratory tract. The white cell count was 23,000. Following this he was discharged and came back in a month with another acute respiratory infection. The temperature was markedly elevated. There is cyanosis and a red throat. The cyanosis increased definitely, the temperature rose to 105°, and he died a few days after he was admitted for the fourth time.

This is the history then of a severe case of bronchial asthma that went on between the ages of two and twenty-one and was accompanied by spells of acute upper respiratory infection as well as bronchial or bronchopneumonic infection.

In the laboratory there were repeated attempts to prove a diagnosis of pulmonary tuberculosis. Many specimens of sputum were examined for tubercle bacilli but none were found. A tuberculin test with a 1:20,000 dilution was negative. One might wish that the sputum had been examined by special concentration methods, but with as much sputum as was present in this case the chances are overwhelmingly in favor of the usual method of examination being positive if tubercle is very present. From the laboratory standpoint we can consider tuberculosis to be ruled out.

The most interesting part of the history is the description of the x-ray films. The only films available for examination at the present time are the ones taken on his third and fourth admissions. From the description in the history at the age of four years the film showed definite bilateral changes at the hilum. At the age of five years the hilar shadows had increased and the left apex was also somewhat involved. At the age of thirteen years the process had spread out from the hilum beyond the midlung field. At the age of twenty-one both upper lobes were involved and there was also an area of increased density in the left lower lobe. Let us look at the x-rays. I shall give you my interpretation and then let the x-ray department tell you what is wrong with this interpretation. The film taken on the third admission shows definite changes through the upper part of both lungs with pathology also at the left base. This other film is a portable taken at the last admission four weeks later.

Dr. AUBREY O. HAMPTON: That was taken two months later.

Dr. KING: Is it a portable?

Dr. HAMPTON: Yes.

Dr. KING: If one had to make a decision from this film alone, I believe that the diagnosis of pulmonary tuberculosis would be justified although the picture is not quite typical of this disease. At the left base I believe there are changes characteristic of bronchiectasis. Can all or most of these changes be due to tuberculosis persisting for seventeen years? Personally, I do not believe so. The x-ray changes seem to me consistent with what we might expect in a very severe asthmatic, and I shall be much interested to see whether this is true.

Dr. Hampton has been much interested in this problem of nontuberculous pulmonary fibrosis, and will, I know, discuss this problem for you.

May I show a few other cases, all of whom had asthma with definite x-ray changes and postmortem examinations. The first case is that of a woman of forty-five. Her asthma began at the age of twelve, but she had no severe symptoms until a year before her death. The x-ray changes are much like those seen in the case under discussion today. Autopsy showed extensive pleuritis, marked nontuberculous pulmonary fibrosis and emphysema. There was no histological evidence of tuberculosis.

The next case had asthma starting at the age of thirteen and continuing until her death at the age of fifty-five. At the last admission her symptoms were largely cardiac. Autopsy showed extensive sclerosis of the pulmonary vessels with marked thickening of the intima. There was also marked nontuberculous pulmonary fibrosis. The heart was very large and was definitely a cor pulmonale. There was a very large liver and massive edema of the extremities. In the oblique film many large emphysematous blebs are shown. It is interesting to speculate as to whether the boy in today's discussion would have developed these blebs and definite blood vessel changes if he had lived longer. There is no x-ray evidence of emphysematous blebs in his lungs at the time of his death.

The next case is a man of fifty-five whose asthma began at the age of thirteen. At the time of examination the x-ray showed marked fibrosis, and the question was raised as to the diagnosis of tuberculosis. The ordinary sputum examination showed no tubercle bacilli and special concentration methods failed to reveal their presence. Finally, however, the sputum was injected into a guinea pig and tubercle bacilli were found. Since this time there has been a definite increase in the pulmonary process and the x-ray now shows a large tuberculous cavity at the left apex. This then is a case of pulmonary fibrosis which is probably on a tuberculous rather than an asthmatic basis. No autopsy has been performed.

The final case is one of nontuberculous fibrosis and there was no history of asthma. As you will see, the film shows marked fibrosis in the upper lobes and the autopsy report was extensive bronchiectasis with nontuberculous pulmonary fibrosis.

Returning now to the patient whom we were considering, I will ask Dr. Hampton to demonstrate the x-ray changes.

Dr. HAMPTON: The first thing that occurred to me after viewing these films was that the epiphyses had not closed. He is twenty-one. He must have been a cretin. He also had a very queer back. I do not understand it at all. It looks as though he should have had some type of arthritis but I see no mention of that. His joint spaces in all the dorsal vertebrae were

markedly narrowed and coming down to the lumbar area he shows the same thing. That may be congenital, just as the failure of closure of the epiphyses of the vertebrae may be due to congenital defect.

I would follow Dr King's reasoning exactly. If I had just this film I would say tuberculosis and bronchiectasis. If I had fluoroscoped him I should probably also add that he had emphysema, that is, if I saw the typical diaphragmatic excursion of emphysema, or asthma, and then I would say he had an enlarged heart.

The scoliosis here prevents one from interpreting the exact shape of the heart, but certainly the right border is prominent, so I might assume that the right side was enlarged. The cardiac change is more obvious in a later film. This film looks as if it were taken back down and the heart is magnified, but the right curve is definitely more prominent than it should be.

DR KING: So you think it is right-sided enlargement?

DR HAMPTON: Yes, probably.

DR KING: If any of the cardiac men are here it would be interesting to have them speak about the electrocardiogram and state whether they think this is definitely a cor pulmonale. I think it is unusual to get a cor pulmonale without more in the lung fields. My feeling is that there will be some but not very marked right-sided cardiac hypertrophy.

DR HAMPTON: I might add that enlargement of the right side could be due to congenital heart disease. I have no definite differential point from the study of these films.

DR KING: You think the picture from the beginning may be congenital heart, or do you think there is bronchial asthma without congenital heart?

DR HAMPTON: I think your previous opinion is more correct.

DR KING: Dr Hampton probably knows something about this case and is a little cautious. Besides the bronchial asthma and fibrosis I should say there was bronchiectasis.

DR HAMPTON: I agree.

DR KING: At the same time there is probably pneumonia to account for the fever and other symptoms.

Are there any other conditions we have to think about? I do not believe so. Malignancy, fungus infection, syphilis, and silicosis are thrown out. As far as we know there is no sign of thrombi emboli or infarcts coming into the picture at the end. So that my diagnosis would be bronchial asthma. I expect that Dr Mallory will find the changes consistent with bronchial asthma, thickening of the bronchi with narrowed lumina and that some of the bronchi and many of the bronchioles are plugged by the definite asthmatic secretion. Then I should think there was emphysema, bronchiectasis of the left lower lobe, bronchopneumonia, probably and perhaps some acute infection in

the upper respiratory tract. I do not believe there is enough to make a diagnosis of retropharyngeal abscess, although there is mention of some bulging in the right pharynx.

DR HAMPTON: Would you like to localize the disease a little more? Do you think it was definitely within the upper lobes?

DR KING: Yes.

DR HAMPTON: With emphysema in the lower lobes? The fibrosis is more localized to the upper lobe than most of our fibrosis cases have been. The right upper lobe should be very small and sclerosed with fibrous tissue and this apparent localization is the only out, as far as I can see. It is too sharply localized for those cases which we have been studying and I am wondering if Dr Mallory will not say that the dullness represents unresolved pneumonia or fibrous organized pneumonia.

DR KING: He has had these changes going on from four years old.

DR FRANCIS M. RACKEMANN: This x-ray picture is not typical of the ordinary asthmatic. I should say that there was some local process going on in the upper lobes to account for the fibrosis. The history suggests to me one of repeated respiratory infection and I should suppose that Dr Mallory would find (I agree with Dr Hampton) more or less bronchopneumonia in these upper areas. Furthermore, I do not believe Dr Mallory will find much plugging of the bronchi. The boy was pretty sick and I think his death was from pneumonia rather than asthma.

To change the subject a little, this boy was rather a pet of the clinic. My impression is that when he came to the clinic as a young boy, he had a marked deformity of his chest and a deformity in the spine as well. He was always cyanotic, always had a wet nose, and was always a little short of breath. So far as his asthma goes, he has behaved fairly typically. He had positive skin tests and in the hospital he was relieved promptly so that he could be discharged in eight days. He responded well to changes in his environment. The interesting point is that at twenty-one his asthma was much improved and that is more or less the rule with people who begin to have asthma early. They outgrow it.

CLINICAL DIAGNOSES

Asthma
Emphysema
Secondary polycythemia
Cor pulmonale

DR DONALD KING'S DIAGNOSES

Bronchial asthma
Bronchiectasis
Bronchopneumonia

ANATOMIC DIAGNOSES

Emphysema, focal
Bronchiectasis
Pulmonary fibrosis
Bronchopneumonia

Cor pulmonale

Chronic passive congestion of the liver, kidneys and spleen

Pleuritis, chronic fibrous, bilateral

Pleuritis, acute fibrinous, left

Scoliosis, left dorsal

PATHOLOGIC DISCUSSION

DR. TRACY B. MALLORY. I think it would be easier for the clinician, the roentgenologist and the pathologist to get together on these cases if we could define the disease that we are dealing with a little better. I question if what Dr. King calls asthma is exactly what I call asthma, and I feel quite sure that what the clinicians call emphysema is not what I call emphysema. There are two sides to bronchial asthma: one is the occurrence of episodes of spasmodic dyspnea, a dyspnea moreover which is specifically characterized by a prolongation of expiration. Any patient subject to fairly frequent attacks of this type must unquestionably be regarded as an asthmatic. But such attacks are physiological in character, may be accompanied by no impairment of function in the intervening intervals, and do not in themselves produce any permanent morphologic changes. A second phase of "asthma" as the term is vernacularly used must be recognized however. A limited number of asthmatics show persistent apparently irreversible functional impairment. In many instances this can be shown to be due to anatomical processes such as emphysema and pulmonary fibrosis, but, since indistinguishable lesions occur frequently in nonasthmatics as well, it seems to me that they should be regarded as complications of asthma rather than as integral parts of the disease. That the asthmatic state may predispose to their development would be rash to deny and is in fact probable although reliable statistical evidence is not yet at hand.

My interpretation of this case is that this boy had these complications and developed the secondary changes in the lung. His lungs showed very numerous scattered patches of marked fibrosis. Within most of these fibrotic areas are dilated bronchioles and small bronchi and there is very widespread bronchiectasis throughout practically all five lobes. The fibrosis was most marked in the right upper and middle lobe. The bronchiectasis was perhaps most marked in the left lower, although it was present in the upper lobes as well.

He had an extreme grade of anatomical emphysema, that is not merely mechanical physiological dilatation of the alveoli as you see it in the midst of an asthmatic paroxysm, but of destruction of alveolar walls and fusion of alveoli into large sacs and blebs. On the right side one bleb measured six centimeters in diameter and in numerous other places there were alveolar sacs from one to 2.5 centimeters in width. The bronchi showed no thickening of the muscle layer and no mucoid secretion. There

was an acute purulent bronchiectasis, with extension into small groups of alveoli and begetting bronchopneumonia.

The heart is one of the severest cor pulmonales that we have seen, with a right ventricle that was within a millimeter as thick as the left.

The remainder of the autopsy was essentially negative. We unfortunately did not examine the thyroid. I wish I had known Dr. Hampton's findings in the epiphyses at the time of the autopsy.

I will show you a lantern slide from this lung. This represents one of the bronchi. The mucous membrane, you will notice, shows marked polypoid projections which are interspaced with hernial-like outpocketings of the mucous membrane halfway through the wall. The musculature, which you can see there and there, is well within normal limits or often slightly less thick than normal. The lumen contains a secretion but it is not the thick mucoid secretion of the asthmatic paroxysm, but a thin purulent one which is simply the evidence of an acute terminal bronchitis. The alveoli in this area tend to average a little bit over normal in size but there are focal areas where there are larger alveoli running up to three or four times the normal. That is particularly marked at this point and you will notice that in the center of that area is a little fibrous scar, also another to the right of it. In other words exactly in that area there has been considerable destruction of lung tissue and the immediately adjacent alveoli have dilated to fill the space and in that way produced a localized focus of emphysema.

This second slide shows a more extensive area of scarring in which all the alveoli have been completely destroyed and in this case the small bronchi have dilated, as the alveoli did in the other section, and are forming definite bronchiectatic cavities. At this point there is a focus of terminal acute pneumonia.

How are we to interpret the pathogenesis of this case? The effort must admittedly be guesswork but I believe we can trace the course with fair probability. As Dr. Rackemann, who had the advantage of following this case in life, pointed out, his asthma in the sense of the frequency and severity of his paroxysms was not excessively severe and in the latter years of his life was actually improving. On the other hand, he did have repeated attacks of real pulmonary infection, presumably pneumonia. I would tie these with the multiple scars found at autopsy and assume that, in one or perhaps each pneumonic attack, organization rather than resolution had occurred. The resulting scars contracted and the surrounding uninvolved pulmonary tissue alveolar in some instances, bronchiolar in others, dilated under the influence of the negative thoracic pressure to fill the space. Asthma paroxysms if persistent would increase the need of such dilatation by maintaining the thorax in a dilated inspiratory position but would not initiate the process. Something in

the allergic state may also predispose to organization rather than resolution

DR HAMPTON Do you make any differentiation of the bronchiectasis at the left base and that within the upper lobes? Is there any difference in the character of the bronchial disease? For instance, do you not show dilatation of the bronchi due to fibrosis just as you showed ruptured alveoli due to fibrosis? Is this bronchiectasis an indication of the fibrosis?

DR MALLORY I think that is one of the not infrequent backgrounds of bronchiectasis

DR HAMPTON It is the cause of bronchiectasis?

DR MALLORY It is one of the causes, not the only one, but I feel sure it is one cause

DR HAMPTON We would have seen the blebs if lateral and oblique views had been taken. Examination of this type of patient is not complete until these views have been taken

CASE 22012

PRESENTATION OF CASE

Eight months before entry the patient a thirty-one year old American housewife, gradually developed frontal headaches, occurring at first at infrequent intervals, usually in the morning, and becoming more frequent and more severe. At about the same time she noted a diminution in vision, at first transient but for the past six months permanent. She had some difficulty in reading, but could read fine print for a short time. She noticed that she could not see so well out at the side of her eyes. Her headaches continued and for the past three months were constant, being present both day and night. During the past two months she had some nausea and vomiting. She developed weakness and for three weeks before admission remained in bed because of her headaches.

Her family and marital histories are non-contributory.

Two years before entry her menses, which had been perfectly regular and normal, stopped. Since then she had occasional hot flashes. There were no other menopausal symptoms.

Physical examination showed a well-developed and nourished woman complaining of frontal headache. Her chest and abdomen were negative.

Neurological examination showed a bitemporal hemianopsia. There was no disturbance in smell. Reflexes were active on both sides and perhaps slightly more so on the right.

The temperature was 98°, the pulse 78. The respirations were 20.

Laboratory examination of the urine was negative. Examination of the blood showed a red cell count of 4,000,000 with a hemoglobin of 60 per cent. The white cell count was 8200, with 68 per cent polymorphonuclears. A Hinton test was negative. A lumbar puncture showed an initial pressure of 340 which went down to 200 after 10 centimeters were removed.

The fluid showed 4 lymphocytes, positive alcohol and ammonium sulphate tests, a total protein of 103 milligrams, and 56.7 milligrams of sugar. The gold sol was 0011233310.

On the third day while being examined she had a sinking spell during which she became unconscious. It was later found that she had had these attacks before. On the fourth day a right transfrontal craniotomy was performed.

Her condition on the day following operation was quite precarious. She had sugar in her urine which was controlled by insulin. She received constant intravenous 5 per cent glucose. Her temperature rose to 104°.

Lumbar punctures performed on the fourth and sixth postoperative days revealed grossly bloody fluid. The pressure reached as high as 550. She rapidly failed and died on the sixth postoperative day.

DIFFERENTIAL DIAGNOSIS

DR EDWIN M. COLE The history is of a young woman who began having headaches which became ever more frequent and severe and eventually were associated with vomiting. Such a story is consistent with gradually developing increased intracranial pressure. At the time that the headaches started she noted a diminution of vision. This symptom often, or one might say regularly, follows increased intracranial pressure of long standing where there has been papilledema for a long time, and a consequent secondary optic atrophy. In this case, however, the visual disturbance seems to have started almost as soon as the increase in intracranial pressure, suggesting a direct or primary interference with the visual mechanism, rather than one secondary to pressure of long standing. Moreover, according to the history, the patient noticed that she particularly found it hard to see out to the side, which suggests a bitemporal hemianopsia. This suggestion is borne out by such a finding in the neurological examination. We know that a lesion causing bitemporal hemianopsia must be at or near the optic chiasm.

In considering visual disturbances we must always think of syphilis as an etiological agent. The history of gradually failing vision is not infrequently met with in central nervous system syphilis. It is occasionally associated with increased intracranial pressure, as in rather acute syphilitic meningitis. In such cases, however, there is usually a rather widespread cranial nerve involvement which is notably lacking here, and the visual field changes are those of concentric constriction of the fields rather than a bitemporal hemianopsia. Moreover, the spinal fluid of syphilitic meningitis has a high cellular content and a positive Wassermann reaction, which is not true in this case. Therefore, I do not think that syphilis need be seriously considered.

Of course, the most common cause of bitem-

poral hemianopsia is enlargement of the pituitary itself, as in tumors of the pituitary gland, or the much rarer tumor arising from the sella turcica. Such patients often complain of visual failure, though occasionally a bitemporal hemianopsia of fairly long standing is overlooked by patients. In addition, they often have considerable headache. They do not have however, an increase in intracranial pressure except in those rare cases of rather long standing, in which the tumor extends upward into the third ventricle. Thus, from the usual pituitary tumor, we would not expect the increased intracranial pressure and vomiting which are important features of this case. The x ray findings in pituitary tumors are typical in showing definite distortion of the sella turcica. In this case the x rays are said to be somewhat suggestive of some enlargement of the sella but apparently there has been no destruction of bone no erosion of the floor of the sella or of the clinoids. Moreover, the presence of increased intracranial pressure suggests that the pituitary is not primarily at fault. I should feel then that a tumor of the pituitary gland or sella turcica is unlikely in this case.

We still must explain then bitemporal hemianopsia associated with a lesion causing increased intracranial pressure which is not inflammatory. A neoplasm involving the stalk of the pituitary, thus pressing on the optic chiasm and also extending upward into the third ventricle so as to block the escape of spinal fluid from the third or either of the lateral ventricles, would, it seems to me, best account for the picture we have here.

A few other findings may throw light on this case. The increase in total protein in the spinal fluid is consistent with neoplasm. An interesting finding is the glandular disturbance suggested by the cessation of the patient's menses, and possibly by the glycosuria before death. These may be sequelae of involvement of the hypothalamus, thus reinforcing our feeling that the lesion may spring from the floor of the third ventricle. Finally we learn that the patient had had periods of unconsciousness during her illness, and though such are met with in many cases of brain tumor they are very frequently associated with tumors of the third ventricle.

In this region cystic tumors possibly springing from embryonal rests, as Rathke pouch tumors, are fairly common. This may be such a one.

CLINICAL DIAGNOSIS

Brain tumor

Dr EDWIN M COLE'S DIAGNOSIS

Cystic tumor of the floor of the third ventricle.

ANATOMIC DIAGNOSES

Pituitary adenoma
Operative wound Craniotomy
Hydrothorax, bilateral
Bronchopneumonia.
Pulmonary atelectasis
Pulmonary congestion
Cholelithiasis
Follicular cysts of the ovary, multiple
Cystitis, acute

PATHOLOGIC DISCUSSION

Dr CHARLES S KUBIK The tumor in this case was a large encapsulated one 4 by 4 by 3 centimeters. It extended upward from the sella between the subthalamic structures of the two hemispheres, spreading them apart and obliterating the third ventricle. Its upper portion covered the foramina of Monro. The lateral ventricles were enlarged to about twice the normal size. This enlargement was obviously the result of almost complete obstruction to the flow of cerebrospinal fluid between lateral ventricles and aqueduct. The findings explain the elevation of intracranial pressure, which as Dr Cole has remarked, is not often observed with tumors in this region. It occurs only when the tumor is unusually large and may fail to occur with tumors not very much smaller than this one.

The optic chiasm, anterior to the tumor, was very badly damaged and I should suspect that all the decussating fibers were destroyed. The sella was enlarged and the floor destroyed so that nothing but the dura separated the tumor from the sphenoid sinus. These changes in the sella were so marked that it is most surprising that the x ray plates of the skull were not more definite. Without definite x ray evidence Dr Cole naturally came to the conclusion that the affair was probably a suprasellar cyst, a tumor which usually does not produce enlargement of the sella.

Microscopic examination revealed pituitary adenoma.

Dr TRACY B MALLORY Very little of importance was found outside the head. There was marked pulmonary congestion and edema with a slight bilateral hydrothorax. A terminal bronchopneumonia was just beginning to be evident. The gallbladder contained a stone and there was an acute hemorrhagic cystitis of the urinary bladder. The ovaries were examined with some care and showed very numerous follicular cysts many primordial follicles and several follicles in various stages of ripening. No corpora lutea were found. The endometrium appeared to be in the resting phase, showing neither proliferation nor secretion.

WHAT SCHOOLS SHOULD BE APPROVED?

In the Division of Civil Service and Registration at the State House in Massachusetts there are eleven licensing groups, the activities of whose licentiates extend from massage of the scalp to chiropody, with intermediate fields more or less comprehensively included, overflowing into pharmacy, veterinary medicine, embalming and certified accounting.

Competence in some of these fields is tested by examination only, as in pharmacy, veterinary medicine and accounting. Admission to examination for licensure to practice in the other fields must be preceded by attendance at an educational institution, a "school" which gives special preparation for the practice in that field.

It is worth while to notice the kind of school from which candidates will be accepted in each case. For chiropody, it must be a "reputable" school, but what is meant by a reputable school is not defined in the statute. For dentistry, the school must be "reputable" and the statute defines what is to be regarded as a reputable dental school, for optometry, the school must be "approved by the board", for nursing, the

school must be "approved by the board", for embalming, the school must be "approved by the board". Even for the latest field for which a board of registration was set up in 1935, hairdressing, the school must be "approved by the board". For barbering, the school must be "properly equipped and conducted" and requires for its establishment a permit from the board which may be revoked if the board sees fit. For medicine only, the school may be conducted without any regard to the approval or disapproval of the board. Why is it that all these other groups have been able to secure from the legislature this protection for the public in the field in which they are interested, and medicine year after year asks protection for the public and cannot get it? It is the right of every physician and of every citizen to know why, and if the answer does not lie on the surface it should be dragged out into the light of day.

Is medicine the least in importance of these groups? Is the field of medicine one in which the issues are of slight significance in the welfare of the state? Other groups indeed, have to do with the health of the people, but who needs more knowledge, who requires greater skill, who has a heavier responsibility than the physician? Who, in his field, has greater power in the matter of life and death than the physician? Yet the embalmer and the hairdresser must come from schools approved by their respective boards. Not so the physician, a diploma mill will do for him.

The answer is not far to seek. In states in which there are no medical schools there has been no hesitation on the part of the legislature in giving the protection which has been sought. It is in states in which there are medical schools that there has been legislative hesitation, but except in Massachusetts the protection of the people has been paramount. Here the delay, and it is merely delay though all too long drawn out, is due to the presence in the state of medical schools which claim it is to their interest that this protection of the public should not be given. The issue is clear, this fact is known, the public must be informed as to what is at stake. It is the duty of the physicians to make clear to the legislature their desire for the protection of the people in the field in which they are practicing. It is their duty to insist on this protection.

Article XIX of the Declaration of Rights of the Constitution of the Commonwealth reads as follows: "The people have a right, in an orderly and peaceable manner, to assemble to consult upon the common good, to give instruction to their representatives, and to request of the legislative body, by way of addresses, petitions, or remonstrances, redress of the wrongs done them, and of the grievances they suffer." No one knows as do the physicians how much suffering unqualified practitioners cause. If they know, let them speak.

JAMES HENRY BREASTED

On December 2, 1935, in New York, died a man of particular importance to students of the early history of medicine—James Henry Breasted. Long regarded as an authority on the history of the ancient peoples of the Near East, particularly those of Egypt, Breasted reached a high point in his long academic life with his translation of the *Edwin Smith Surgical Papyrus*. From the viewpoint of the Egyptologist, this work threw new light on Egyptian philology and confirmed the impression, gained by scholars of the past that the people of the Nile were empiricists. For the medical historian, Breasted's brilliant translation completely revolutionized all previous concepts of pre-Hippocratic surgery. For the contents of the *Edwin Smith Papyrus* were disclosed, no one knew that scientific surgery existed in the IV Dynasty (2900 B.C.) or that men of that period could think clearly and rationalize their ideas in the spirit of modern times. The fine orderliness of the case histories surprised even the learned Egyptologist as is evinced by Breasted's remarks in his preface:

"I felt as if I had been peering through a newly revealed window, opening upon the once impenetrable gloom enveloping man's earliest endeavors to understand the world he lived in. Were it not for Breasted, the knowledge of our medical 'Oriental Heritage' might for years have been delayed.

The translator, in dealing with an obscure language, has several courses open to him. He may give a literal rendition, translate the original idea into what he conceives to be a current meaning, or he may transliterate into correct but, nevertheless uninspired modern colloquial English. All have their faults and Breasted, in his translation of the *Edwin Smith Surgical Papyrus*, avoided each of them. Not only did he summon technical help in regard to particular words from his friends in the medical profession, but he culled the "Ancient Records of Egypt" and made full use of the great Berlin 'Wörterbuch der ägyptischen Sprache' in order to arrive at more precise meanings. In spite of this meticulousness, he retained a remarkable atmosphere of the ancients, not unlike that of the King James version of the Bible. Instead of, "If you examine anyone with a dislocation," he makes the unknown Egyptian surgeon a more vivid personality "If thou examinest a man having a dislocation." The illusion of sitting at the feet of the "Ancient Teacher" is thereby retained. Breasted did for the *Edwin Smith Surgical Papyrus* what Edward Fitzgerald did for the "Quatrains" of Omar Khayyám.

Thus is ended the career of a scholar and scientist, and, we might add, a poet. During the Middle Kingdom in Egypt, a certain noble in

enumerating his own virtues, inscribed on the walls of his tomb "I gave bread to the hungry, beer to the thirsty, clothes to the naked." Could there not as well be inscribed on James Henry Breasted's "House of Eternity" "I gave to them the wisdom of the past."

THE ONE HUNDRED AND FIFTY FIFTH
MEETING OF THE MASSACHUSETTS
MEDICAL SOCIETY JUNE 8, 9 AND 10,
1936

For the third time in its history the annual meeting of the Massachusetts Medical Society will be held in Springfield. This is especially gratifying because the Hampden District Medical Society with a membership of well over three hundred maintains high standards of professional and civic activities and the city is noted for its hospitality. The hospitals which represent in a definite way the standing of its physicians have over eleven hundred beds and will provide abundant material for clinics.

The hotel accommodations are ample and the local committee of arrangements together with the state society officials are developing programs of great excellence for the instruction of the doctors and the entertainment of the guests. When the 1926 meeting was held in Springfield the Society elected for its president, for the then ensuing two years, Dr. John Matthews Birnie. His administration made a notable contribution to medical history in Massachusetts in the creation of an endowment for a home for the Society. In course of future years, this will grow under the able management of our treasurer, Dr. Charles S. Butler. The fund now amounts to about fifty thousand dollars and will be available whenever the Boston Medical Library is in a position to utilize the rooms now occupied by the Society.

Another interesting feature of the meeting in 1926 was the realization of the ambition of Dr. James S. Stone, who, in association with Dr. David Parker of Manchester, New Hampshire, devised the plan for the New England Medical Council which was worked out during this session. This organization was the constructive factor in bringing the several New England State Medical Societies into more harmonious relations. For several years meetings were held for the discussion of problems of common interest. One result was the association of New Hampshire and Vermont in the publication of the proceedings of these two state societies in *The New England Journal of Medicine*.

Springfield doctors are progressive and resourceful and may be considering the adoption of plans which will give to the parent society suggestions for other methods to increase the influence of the medical profession in this part of the country. The year 1936 will be an important period in the history of Springfield, for in May the city will celebrate the three

hundredth anniversary of its founding, and there will be at hand much of interest to visitors.

The doctors have been studying the medical history of the city. Some papers have been written and others are in preparation which when published will be noteworthy. This work has been sponsored by the Springfield Academy of Medicine.

These references to the Springfield meeting will be followed by a series of editorials, prepared by the Chairmen of the Scientific Sections, which will inform the Fellows of the character and scope of the scientific papers and discussions. These men are leaders in their several departments and their announcements warrant careful attention.

The Committee of Arrangements will give detailed accounts of the social features of the meetings.

Two addresses will be of particular interest. The Annual Oration by Dr. Reginald Fitz will cover significant phases of medical history. His reputation is a guarantee of the entertainment in store.

The Shattuck Lecture has always been an important contribution to the program. Although no announcement of the speaker has been made, the committee in charge of the selection has always provided an eminent contributor to medical literature. As soon as the committee releases this information, it will be published.

The Committee of Arrangements will publish from time to time details of what is being prepared. Read the *Journal* for this information and set aside June 8, 9, and 10 for a three days' vacation and postgraduate instruction.

SECTION OF OBSTETRICS AND GYNECOLOGY*

C. J. KIRKHAM, M.D., R. S. TITUS, M.D.
Chairman Secretary
54 Commonwealth Ave., 472 Commonwealth Ave.,
Boston, Mass. Boston, Mass.

THE VALUE OF ROENTGENOGRAPHY IN ADVANCED STAGES OF PREGNANCY

Roentgenology has made rapid strides within recent years and has become a valuable adjunct in the diagnostic armamentarium of the obstetrician also a therapeutic guide. The value derived is proportionate to the extent to which it is utilized and is enhanced by the cooperation of the Clinical Staff with the roentgenologist.

We may divide the problems requiring the aid of roentgenology into two groups both particularly important in the latter stages of pregnancy.

1. Maternal
2. Fetal

1. Maternal

A. Pelvic

Types of pelvis
Injuries
Infections
Neoplasms involving the bones
Separation of the symphysis pubis
Measurements

B. Uterine

Tumors
Placenta praevia
Hydramnios

C. Urinary

Pyelitis
Pregnancy hydronephrosis
Calculi
Congenital abnormalities and other conditions

D. Pulmonary

Tuberculosis
Congestion
Nontuberculous lesions

E. Cardiovascular

Decompensation
Valvular lesions
Congenital anomalies

F. False pregnancies

The roentgenographic study of the pelvis reveals the type of pelvis with which we are dealing. Caldwell and Molloy classify the pelvis on a morphological basis into the four following groups:

1. Gynecoid
2. Anthropoid
3. Android
4. Platypelloid

They believe that all of these types bear a definite relation to the engagement of the fetal head and have a resultant effect on labor.

Deformities resulting from congenital abnormalities or metabolic diseases such as rickets, osteomalacia and hyperparathyroidism (osteitis fibrosa cystica) are easily recognizable.

Posttraumatic changes in the pelvis and the results of inflammation and neoplastic changes are encountered. Among these may be mentioned old fractures healed and active tuberculous, especially of the hip joint, osteomyelitis of any of the pelvic bones, primary or metastatic neoplasms.

The demonstration of the separation of symphysis pubis or of abnormal mobility of the pubic bones is of great value to the obstetrician.

Roentgenographic methods of measuring the female pelvis are well recognized procedures and have proved more accurate than the external measurements. These methods are of two types, (1) linear, which is at present the one most commonly used and (2) the volumetric method advocated by Dr. R. P. Ball.

From my observations the roentgenologist by stereoscopic study can usually determine the relation and proportion of the fetal head to the pelvis without the aid of direct measurements.

Uterine tumors and ovarian cysts are often demonstrated but with greater difficulty than in nonpregnant individuals because the use of opaque media is restricted during pregnancy.

Several methods are employed to determine the presence of placenta praevia. This condition can occasionally be demonstrated in the plain film by the presence of a semilunar area of increased density in the lower portion of the uterus. The injection of a small amount of sodium or strontium iodide (two and a half per cent) in the bladder will reveal a distinct displacement of the fetal head away from the bladder due to the interposition of the placental mass. This is a very helpful and harmless procedure.

Amniography. The injection of strontium iodide into the amniotic fluid advocated by Menees, Müller and Holly is regarded as a dangerous procedure, although it beautifully outlines the placenta. By this method the sex of the fetus can sometimes be determined.

Hydramnios is characterized roentgenographically by the disproportionate enlargement of the uterus compared with the size of the fetus. Intravenous urography has simplified and

* Series of short selected articles by members of the Section is being published weekly. Comments and questions by subscribers are solicited and will be discussed by members of the Section.

expanded the study of the physiological changes of the urinary tract during pregnancy. These are enlargement of the kidneys, dilatation of the renal pelvis and calices, more common on the right side, dilatation, kinks, outward displacement of the middle third of the ureters and pressure on the bladder. From these physiological changes various pathological conditions may result.

Pyelitis is a common complication of pregnancy. Although this condition cannot be readily recognized on the roentgenogram, frequently a diagnosis can be made from the characteristic fuzziness in the outlines of the calices and pelvis. It is important to note the normal involution of the urinary tract which takes place promptly after delivery.

Congenital anomalies, the presence of calculi, tuberculosis and tumors of the urinary tract merit the same consideration as in the non-pregnant individual.

Pregnancy has a deleterious effect on pulmonary tuberculosis and roentgenology undoubtedly is the most reliable method we have in following the progress of the infection. The same applies to nontuberculous lesions as well, such as bronchiectasis, lung abscess, etc. One should not misinterpret the physiological increase in the pulmonary markings during pregnancy.

Changes in the cardiac measurements whether resulting from progressive failure or improvement following cardiac therapy are noted. The effect of the elevated diaphragm on the contour of the heart is still a disputed question.

Occasionally anxious women present themselves with all the signs of an advanced pregnancy. A simple radiographic examination will indicate that the pregnancy was falsely suspected.

2 Fetal

With the progress of pregnancy to the latter stages, the fetus itself presents a group of problems:

- A Single and multiple pregnancies
- B True position and presentation of fetus
- C Disproportion of the head
- D Malformations and maldevelopments
- E Size of fetus and its relation to viability
- F Intrauterine death of fetus

Roentgenographically it is simple to differentiate the various positions. Prior to the engagement of the presenting part the position of the fetus may change at any time. We have observed a fetus change position five to six times within one hour during a pnelvographic examination.

Stereoscopic examination assists in further visualizing the position of the presenting structures as they engage in the pelvis. Thus the head may be seen engaged in any one of the oblique diameters, anterior or posterior position.

The same applies to the various other presentations. The only time the fetal head is permanently engaged is during active labor.

Malformations of the fetal skeleton are sometimes demonstrated in utero.

Monstrosities are easily discernible, the most common, anencephalon, is characterized by the absence of the normal contour of the head which is small and deformed with a rudimentary cervical and shortened thoracic spine.

In hydrocephalus the head is very large, the cranial bones are thin, the sutures considerably widened, and the fontanelles indistinct.

In breech presentations where the head lies in the fundus it may appear abnormally large. This apparent enlargement is a photographic illusion because the head in the abdomen lies at a greater distance from the film, as compared with the head lying in the pelvis. This may simulate hydrocephalus which can easily be ruled out, however, by observing the sutures which are not widened and the presence of clearly outlined fontanelles.

As previously pointed out, stereoscopic studies and measurements are of considerable value in deciding the question of disproportion in which the obstetrician is vitally interested.

Death of the fetus. Fetal death is indicated by the overlapping of the cranial bones ("Spaulding's Sign"), the head is small and the vertex is pointed. These changes are due to intrauterine cranial postmortem changes, which can be demonstrated roentgenographically twenty-four to seventy-two hours after the death of a fetus.

When the fetus is macerated the small parts are disorganized, the fetus appears to be in a crouched position, and the spine shortened. When looking for "Spaulding's Sign" one must be certain that the patient is not in labor as the uterine contractions will produce overlapping of the bones during moulding of the head.

The size of the fetus and *pari passu*, its viability can be established by measuring the fronto-occipital diameter as was recently emphasized in an excellent contribution by Stewart Clifford. He has pointed out that if this diameter was between eight and nine centimeters the baby was found to weigh less than three pounds. An occipital frontal diameter of less than ten centimeters indicates that the weight of the baby is less than four pounds, occipital frontal diameter 10.5, the minimum weight is four pounds, with a diameter greater than eleven centimeters the minimum weight is five pounds.

His experience further shows that the mortality for infants of less than five pounds was between 29 and 48 per cent. The mortality for infants weighing from five to six pounds was less than 3 per cent.

Since the fetal mortality is thus co-related with fetal weight, we have a valuable criterion

in determining the probable viability of the fetus when the question of interruption of pregnancy arises. Recent studies have indicated that the normal fetus gains weight in utero at the rate of five to six ounces per week during the seventh and eighth lunar months and eight to twelve ounces per week in the last two months of pregnancy. In view of this accelerated gain in weight during the last trimester any delay in the interruption of pregnancy deliberately occasioned without adding to the maternal danger will tend to insure viability.

In addition, prematurely induced termination of pregnancy in appropriate cases when the viability of the fetus is anticipated may be a definite factor in reducing maternal morbidity and may even avoid mortality.

The indications for the interruption of pregnancy such as toxemia, cardiac decompensation, uterine bleeding, active pulmonary lesion, urinary tract infections etc. are well known.

Thus cephalography and cephalometry play important roles in aiding the obstetrician in the conduct of labor with due consideration to the fetus as well as the mother.

The question of danger associated with the use of roentgenography during pregnancy is often raised. If due precautions are taken against excessive exposure no untoward effects are to be expected.

In the author's experience at the Boston Lying In Hospital, and in his own practice he never encountered any effect to contraindicate its use during pregnancy.

CORRESPONDENCE

THE REPORTING OF ANTERIOR POLIOMYELITIS

The Commonwealth of Massachusetts
Department of Public Health
State House Boston

December 26 1935

Editor *New England Journal of Medicine*

During recent years much confusion has arisen regarding the actual prevalence of poliomyelitis due to the fact that no differentiation has been made in the official reports between paralytic and nonparalytic cases. The better recognition of the nonparalytic type of case and its inclusion today in the reports as contrasted with its noninclusion in former years have given a false impression as to the prevalence of the disease as compared with these other years.

In order to avoid so far as possible further confusion, the Public Health Council has voted that effective January 1 1936 all cases of anterior poliomyelitis shall be reported as "paralytic" or nonparalytic (preparalytic) cases. This means that all reports of infections to the boards of health should be made under one or the other of these classifications and that if a nonparalytic or preparalytic case subsequently develops a paralysis a

supplemental report should be made to the board of health in order to change the classification.

May I through your columns request the hearty cooperation of the medical profession in making such a classification of their reports in order that a more nearly accurate picture of the current prevalence of the disease may be available in the future.

Very truly yours

HENRY D CHADWICK M.D.
Commissioner of Public Health

ELECTRO-CHOLECYSTECTOMY

December 18 1935

Editor *New England Journal of Medicine*

In this *Journal* October 1930¹ and again in September² and October³ 1935 were published descriptions of an operation which I have termed electro-surgical cholecystectomy.⁴ Briefly The gallbladder is split to the cystic duct, which is tied if this can be done safely the redundant portions are trimmed away with the electrosurgical cutting current, and the remainder treated by fulguration or light contact coagulation with the bitermal coagulating current. Drainage is used. This is a modification of a procedure devised by Pribram⁵ which he termed "molekylase". The gallbladder is split to the cystic duct which is tied and cut, and the whole mucosa treated with the actual canter (hot iron) the leaves of the vesicle are then sewed together and the abdominal wound closed without drainage. It has occurred to me that instead of the term "electrosurgical cholecystectomy" a simplified compound word descriptive of the process would be preferable. I suggest *electro-cholecystectomy*.

DISCUSSION ON THE ANNUAL REGISTRATION OF PHYSICIANS

December 18 1935

Editor *New England Journal of Medicine*

It is unfortunate when a certain few take it upon themselves and prematurely discuss in the newspapers the annual registration of physicians. That topic should first be settled by the members of the medical profession as it concerns solely the licensed physicians of Massachusetts.

The subject is not new because several years ago the writer advocated such annual registration of physicians, which article was printed in the *New England Journal of Medicine* but no one paid any attention to what was said. Recently in the issue of December 14 1935 the State of New York was mentioned as having benefited from such a law. Since New York is being used as an example why

not include other legislation that has been passed in New York which certainly has benefited the medical profession, namely, (a) permitting the designation "Doctor" to be used only by physicians (b) good Workmen's Compensation laws whereby the insurance companies don't have the upper hand but the medical society has it, (c) last but not least, the medical school is not mentioned on the certificate of registration, which is absolutely not necessary

Also in the above-mentioned issue of *The New England Journal of Medicine* a \$2.00 yearly tax was advocated although it was felt that some physicians might object to it. If money raised by such a law should be used for the appointment of "Inspectors" who should be registered physicians in Massachusetts, and such appointments should be made only after passing a competitive Civil Service Examination, and whose duty should be that of checking up on all persons who are practicing medicine illegally such as is now being done by pharmacists, chiropractors, chiropractors, optometrists and many others, then the registered physicians would be glad to pay such a tax.

In addition, the money so collected should also be used to acquaint the public with the use and meaning of the designation "Doctor" and also with the significance of those big signs, "Foot Specialist," "Podiatrist," etc. It is time something was done to eliminate these misleading terms. Passage of another law limiting the use of the term "Doctor" to registered physicians only and passage of better Workmen's Compensation laws are more important than the annual registration of physicians.

Should the General Court or medical profession object to a \$2.00 annual tax, then the extra expense could be met by increasing the fee for those taking the licensing examinations and those seeking reciprocity.

Very truly yours,

BERNARD ZUCKERMAN, M.D.

Dorchester, Mass.

NOTICES

WORCESTER STATE HOSPITAL, WORCESTER, MASS

6 PSYCHIATRIC INTERSHIPS OF 12 MONTHS TO BEGIN
JULY 1, 1936

A rotating service on medical and surgical wards, male and female psychiatric wards

Organized instruction in eleven courses

Registration before March 1, 1936

Examination date March 15, 1936, at 9 A.M. at the hospital

The hospital provides maintenance

Graduates (unmarried men) of Class A Medical Schools who have completed an accredited internship in medicine are eligible

Applications should be addressed to the

DIRECTOR OF CLINICAL PSYCHIATRY

MEDICAL CLINIC AND STAFF ROUNDS AT THE PETER BENT BRIGHAM HOSPITAL

At 3 30 P.M. on Thursday, January 9, in the Amphitheatre of the Peter Bent Brigham Hospital, Dr. Henry A. Christian, Physician-in-Chief, Hersey Professor of the Theory and Practice of Physic in the Harvard Medical School, will give a medical clinic. To it are cordially invited practitioners and medical students.

On Saturdays in the wards of the Peter Bent Brigham Hospital, from 10 to 12, staff rounds will be conducted by Dr. Christian.

REPORTS AND NOTICES OF MEETINGS

FAULKNER HOSPITAL CLINICAL MEETING

The December clinical meeting was held at the Faulkner Hospital on Thursday afternoon, December 5, at 5 00 P.M.

Two unusual cases that had come to autopsy were presented. The first one was a case of encephalomalacia widely scattered over the surface of the brain. Clinically the case had been obviously one of some disturbance in the central nervous system. The spinal fluid was negative. Although suspicion was aroused of a tumor of the corpus callosum, this was finally ruled out and a diffuse vascular lesion of the brain was diagnosed. It happened that the patient had a leukocyte count of 25,000 without any evidence of infection. The red blood count was 6,500,000. It was thought that possibly there might be a polycythemia with multiple thrombi in the cerebral vessels. The striking feature at autopsy was the fact that there was no vascular lesion of any sort to account for the multiple areas of softening of the brain and the etiology of the cerebral lesion still remains obscure.

The other case was apparently a simple one of bronchopneumonia which in the course of three weeks went to a fatal termination. The interesting feature in this case was the fact that during life it was suspected that he might have the epidemic disease which overran this country in 1918-1919. This suspicion was aroused because the leukocyte count was not elevated and the x-ray picture of the chest showed a bilateral bronchopneumonia starting in the hilus of both lungs. In addition at the right base, the process extended to the periphery in the x-ray picture which may have been due to a secondary invading organism or an extension of the epidemic disease. This suspicion was confirmed at autopsy by the finding of the hyaline-like membrane in the alveolar spaces of the lung which has been described by Wolbach as peculiar to this disease.

Opportunity was taken with the presentation of this case to emphasize the fact that the designation *influenza* is unfortunate in regard to this epidemic disease. The cause of the epidemic disease has never been ascertained. It is a disease which is very apt to have secondary invading organisms, such

as the influenza bacilli the streptococci or the pneumococcus which produce lesions in the lungs and may cause death. These secondary invading organisms mask the lesion produced by the epidemic disease by the time the case comes to autopsy. In 1928 a case of the epidemic disease suspected by x-ray examination and confirmed at autopsy by the presence of the hyaline membrane developed in Petersham Massachusetts and now this case has been discovered in Boston this autumn. Each winter cases are spoken of by practitioners as influenzal pneumonia. Probably many of these are not the epidemic disease but it seems likely that some of them are the epidemic disease which became so universal in 1918 and 1919.

Following the presentation of these two cases Dr. Tracy J. Putnam gave a splendid presentation of the surgical treatment for athetosis. He showed some lantern slides and moving pictures of cases of athetosis before and after operation and also showed a case which had been operated on at the Fankner Hospital a few weeks before with very decided improvement.

He called attention to the fact that the disease consists of degenerative changes in certain areas in the brain. The etiology of this degeneration is not clear, but may be due to asphyxia at birth as many of the cases are congenital. On the other hand some of the cases develop in adult life which makes the etiology of these cases more obscure. The areas of the brain which degenerate send fibers down the cord in areas which have been localized and the surgical treatment consists in cutting these fibers as high up in the cord as possible not with the idea of curing the condition but with the idea of interrupting the distressing muscular movements which are produced by the degenerative changes in the brain which send impulses down along these fibers. In order to eliminate as many of the abnormal muscular movements as possible the fibers in the cord must be cut as high as is practicable in the cervical region. Torticollis is one of the distressing symptoms in some of these cases and to correct this the spinal accessory nerves are cut. This operative procedure offers great relief to many of the distressing symptoms in these exceedingly unfortunate individuals.

GREATER BOSTON MEDICAL SOCIETY

This monthly meeting of the Greater Boston Medical Society was held in the auditorium of the Beth Israel Hospital Tuesday evening December third. Dr. Harry Linenthal, President of the society presided. The evening was devoted to a consideration of liver function tests and the dietetic treatment of liver disease and hypercholesterolemia. Dr. Siegfried J. Thannhauser, Chief of Research at the Boston Dispensary and Associate Professor of Clinical Medicine at Tufts Medical School, was the principal speaker.

Dr. Thannhauser began his address by citing the manifold functions of the liver in anabolism

and katabolism. He stressed the multiplicity of functions the organ has in relation to protein, fat, carbohydrates, cholesterol, bile phosphatase, etc. In addition he mentioned the detoxifying function and the rôle the organ plays as an important subdivision of the reticulo-endothelial system. The first test of function discussed by the speaker was the galactose tolerance test. Forty grams of galactose are given by mouth and all but three grams of this should be absorbed and not appear in the urine in the following twenty-four hours. This test fails in many cases and is not a good one where there is early cirrhosis or circumscribed liver disease. It is a good test when there is severe general disease of the liver and it often helps to distinguish simple catarrhal jaundice or acute yellow atrophy from obstructive jaundice. Other tests, depending on the liver's detoxifying function, were next discussed. The liver is supposed to deaminate amino-acids and there is an increase in these substances (tyrosine, leucine, etc.) in blood and urine in severe diseases of the liver. An amino-acid tolerance test has also been devised but the liver is not the only deaminizer (the kidneys can also perform this function and most all organs can do it to greater or lesser extent). The liver forms urea from ammonia and is the only organ that does this and a rise in the amount of ammonia in the blood denotes liver damage. This test for ammonia has to be done immediately on taking the blood. The Takata-Ara test (reading of a serum flocculation reaction with mercuric chloride) was next mentioned. The difficulty with this test is that it is said to be occasionally positive in nephritis as well as in cirrhosis of the liver. The cholesterol-cholesterol-ester ratio (in blood serum) is an excellent test for liver function. Cholesterol esters being markedly lowered in severe parenchymal liver damage, whereas in obstruction the ratio remains the same even though the total of the two is increased. Dr. Thannhauser also mentioned the bromsulphalein and other dye tests which are essentially measures of secretory function and added that they are not very sensitive. In summary he stressed the importance of doing several tests with all the varied functions of the liver in view and he believes that the galactose ammonia in the blood and the cholesterol-cholesterol-ester ratio are the best tests.

Dr. Thannhauser pointed out that the dietetic treatment of diseases of the liver is not employed as a matter of course as in Bright's disease. It is probably advisable to give at least 70 per cent of the calories as carbohydrate and restrict protein (even to forty grams a day) and fat. Small doses of insulin before the carbohydrate meal are of doubtful value. Marked protein limitation (especially because of the lack of urea formation by the sick liver) is necessary in acute disease and is wise preventive in chronic diseases of the liver. There is a difference between animal and vegetable protein in that the latter is better to use because no autolysis

takes place preliminary to eating, whereas in animal proteins autolysis before ingestion is the rule. Restriction of fat is also very desirable, and vegetable fats, the speaker believes, are to be used entirely, and garlic and onions, which increase bile secretion, can be used to advantage. The ideal diet thus embraces a rich content of carbohydrate plus small amounts of vegetable protein and fat. Sample diet sheets were demonstrated and passed around.

In discussing the pathogenesis of hypercholesterolemia Dr Thannhauser demonstrated the analogy and the difference between this disease and gout, in both diseases a physiological substance of intermediary metabolism becomes a cause of morbidity because of its retention. In so-called essential xanthomatosis (demonstrated by the presence and microscopic appearance of so-called "foam cells") cholesterol is stored, destroys the cell, and finally leaves a granulomatous scar. Cases of this disease naturally improve on a cholesterol-free diet. Inasmuch as animal cholesterol is the only one absorbed as such, vegetable oils are the only ones permitted. A pure vegetable diet is not a source of absorbable sterols. Improvement takes place in four to eight weeks. Hypercholesterolemia from other causes (hyperthyroidism) may also be benefited by an animal-cholesterol-free diet.

Dr Chester Jones, of the Massachusetts General Hospital, opened the discussion. His attitude about liver function tests is that of a conservative. Except in rare cases, liver function tests are no better than experienced clinical judgment. As far as diagnosis is concerned such tests are usually disappointing, and they frequently are found wanting in critical cases. The speaker mentioned a severe case of yellow atrophy due to arsenic where the patient had always taken care of galactose. The diagnostic value of all such tests is overrated and a plea was made for intelligent use of simple tests that are combined with clinical judgment. As far as prognosis is concerned, however, the tests are of very definite value. For a repetition of them may show a trend, which is always important. A simple good practical test is recording the urinary output. If this rises spontaneously, the prognosis in acute liver disease becomes better. The risk of hemorrhage, a very important consideration if surgery is contemplated, is a hard one to evaluate. A study of coagulation time, sedimentation rate, and so-called "venous stasis bleeding time" sometimes helps. As far as treatment is concerned, Dr Jones wishes to emphasize the value of carbohydrate. Insulin is a very doubtful adjunct. Parenteral as well as enteral administration of sugar is often necessary or at least wise. Rectal administration is of little practical value. Although fat and protein intake should be kept at a low level, in chronic longstanding disease, Dr Jones believes many patients suffer from protein lack, because of anorexia and because of the loss of protein into the ascitic

fluid if that is present. Milk and liver protein (shown by Whipple to be of value in raising serum protein) are indicated in such instances.

Dr I. R. Jankelson wished to stress the value of icteric index and van den Bergh reactions. He has also been doing some work on the intravenous galactose tolerance test, bilirubin tests, and tyrosine-content of the blood. He pointed out the two great difficulties encountered in liver function studies, namely, the great reserve of the liver and its great recuperative power. Insulin may be of definite value, if only because it increases the appetite. Dr Jankelson asked about insulin in hypercholesterolemia, but Dr Thannhauser said he had had no experience with it.

Dr Benjamin Banks cited some of his experimental work on dogs in which he showed conclusively that the liver stores more glycogen when glucose is given by vein than by other routes.

In closing, Dr Thannhauser emphasized the fact that function tests are never good in themselves but are only to be considered in connection with clinical facts. Hypercholesterolemia secondary to chronic biliary cirrhosis must be distinguished from essential or primary xanthomatosis with hypercholesterolemia. Dr Thannhauser would restrict protein more vigorously than Dr Jones, even in chronic liver disease.

The interesting meeting was adjourned by the president shortly after ten o'clock.

CARNEY HOSPITAL CLINICAL MEETING

The last clinical meeting of the Carney Hospital was held on December 2, 1935, at 8 30 P.M. The entire meeting was given over to a symposium on back pain.

Dr A. R. MacAusland presented the various orthopedic conditions which could be considered the etiological agent for such pain. He stressed the importance of consultations with specialists in those fields in which conditions arise which produce back pain.

Dr W. J. Mixter presented the differential diagnosis from a neurosurgical point of view. He emphasized the use of the lumbar puncture and the lipiodol injection. He also stated that the chemistry of the spinal fluid in many cases makes the diagnosis.

Dr R. J. Heffernan presented back pain from the gynecological aspect. He also stressed the need for consultation and said that fibroids per se do not necessarily cause pain in the back, but that the accompanying congestion of the pelvic organs is probably the main factor.

The urological point of view was presented by Dr Roger Graves. In his opinion, kidney disease rarely gives the type of pain that was under discussion. He also brought out that congestion of the pelvic organs was certainly a factor to be considered and that such things as a full bladder and an infected and congested prostate could cause

pain in the lumbosacral region Metastatic implantations from the prostate to the vertebrae were emphasized. A general discussion by members of the staff and visitors followed

BOSTON PATHOLOGICAL SOCIETY

The stated meeting of the Boston Pathological Society was held in the Pathological laboratories of the Children's Hospital on Friday evening December 6. Members and guests gathered early to have the opportunity of examining interesting specimens and microscopic sections from the pathological department of the hospital and to allow informal study and discussion of these cases. The meeting was called to order at eight forty-five by Dr. Shields Warren.

The first talk was by Dr. Ralph Miller of Dartmouth College Medical School on Secondary Nodules of Lymphatic Tissue. These nodules have been given a variety of names: central regions of lymphatic tissue, germinal centers, degeneration centers, or white centers of peripheral nodules. They are most prominent in childhood and are of commonest occurrence in areas where there is inflammation or necrosis. The various types of these nodules (active necrotic epithelioid, hyaline and reticular) were discussed and depicted on lantern slides made from microscopic sections. The speaker discussed the relation of these nodules to immunization (especially so-called cellular immunity) and summarized the indirect evidence which seems to link them with this function of the body—their location in sites of inflammation, their appearance only after contact with an external agent, and their increase in number where bacteria are most numerous. In response to a question about their vascular supply the speaker added that, so far as he can tell, their circulation is not an open but a closed one.

Dr. Mortimer Warren of the Maine General Hospital next discussed two interesting cases of leukemia. The first was of the chronic lymphatic type in a sixty-six year old Indian male and the second was of an acute type in a nine months old female infant. There was considerable question concerning the latter as to whether it was an acute myeloid type or perhaps monoblastic (endothelioid type of cell) in origin. In the discussion of the cases the short duration of leukemia in children was brought out as well as the frequent difficulty in classification of the younger groups among the patients.

Dr. Cecil Krakower of the Children's Hospital Boston gave the final paper on the program a discussion of 'Unusual Terminations of Leukemia in Childhood'. Dr. Krakower's presentation was limited to six cases of the forty seen in the past ten years at the Children's Hospital. All six showed very striking bone marrow pictures: hypoplasia to complete aplasia of the marrow. There was noted a marked paucity of infiltration of leukemic cells in the organs at postmortem examination apparently

due to a disappearance of the cells just prior to death.

At a business meeting following the papers, Dr. Monroe J. Schlesinger was elected President, and Dr. Beach Hazard Secretary of the Society. Refreshments were served.

THE CUTTER LECTURE IN PREVENTIVE MEDICINE

The Cutter Lecture in Preventive Medicine for 1935 was delivered December 4 at the Harvard Medical School by Dr. Milton J. Rosenau, recently retired Charles Wilder Professor of Preventive Medicine and Hygiene at the Harvard Medical School. Dr. Rosenau spoke on the subject of "Epidemics."

Epidemiology does not confine itself to infectious or contagious diseases, but is the study of disease as a mass phenomenon. Diseases affect the community of individuals much as they affect the community of cells which compose our bodies.

Dr. Rosenau told of his "discovery" of an epidemic of bubonic plague which occurred in Stratford-on-Avon in 1664. While in Stratford-on-Avon in 1914 at the celebration of the 350th anniversary of Shakespeare's birth he examined the parish register and found the typical rise and fall of mortality that characterize an epidemic. This was but a part of the great pandemic that swept all of Europe in the sixteenth century and cost some twenty-five million lives. Such great catastrophes as this were of great import in shaping the history of the world.

The typhoid epidemics of Chicago were cited as examples of water-borne epidemics. Chicago formerly took her drinking water from Lake Michigan only a relatively short distance from the vicinity where all of the city sewage was emptied. Deaths from typhoid fever during this era were extremely numerous, averaging around one thousand each year. With the installation of the drainage canal and the disposal of the sewage into the Illinois River there was an immediate and striking decrease in the incidence of typhoid and dysenteric disease. Soon the city claimed complete freedom from the disease. Then in 1923 a cross connection between the water and sewer systems precipitated another epidemic of typhoid localized in one part of the city. Diagnoses of cases irregularly scattered throughout the city were soon made. Dr. Rosenau emphasized the fact that these latter cases were not "new" but that it had become "unfashionable" to diagnose typhoid in Chicago, and the outbreak of the localized epidemic had merely served to "bring under cover cases to light."

The number of cases required to justify the designation of an epidemic is indefinite and largely a matter of relativity. Twenty years ago rates of typhoid of 15 to 20 were called "residual" or "normal" rates in the United States. At the same time rates in Berlin and Paris were as low as 2 and a rise to 15 or 20 would have promptly been considered

as an epidemic in those cities. The definition of an epidemic is thus seen to be largely an academic matter.

A complete understanding of a disease necessitates a knowledge of its clinical aspects, its laboratory data, and its epidemiology. Epidemiology's contributions to our knowledge of a disease are exemplified by the researches of Peter Parnum in an epidemic of measles which occurred in the Faroe Islands in 1846. Previous to that date there had been no measles on these islands for a period of sixty-five years, a fact that showed there was no chronic carrier of the disease. Then a person left Copenhagen in the incubation stage of the disease, and arrived on the islands while in the infectious period, with the result that 6000 persons were involved in an epidemic. Only those persons over sixty-five years of age, and those in isolated districts escaped infection. Parnum determined by epidemiological studies that there is no inherited immunity, that one infection produces life-long immunity, that the incubation period is fourteen days, and that all ages are susceptible. (Later studies have shown that newborn babies of mothers who have had the disease are immune for a period of several months after birth, due to passage of antibodies through the placenta.) He learned that the disease is infectious in the pre-eruptive period, and that it is not communicable in the desquamative stage. Its highest fatality is in the aged and young.

Errors have been made in epidemiology as in most other sciences. Malaria was first believed to be a water-borne disease by Ronald Ross, all materials brought through the port of San Francisco were put through sterilizing processes during the bubonic plague, while rats were completely disregarded, letters coming from yellow fever districts were sterilized for years. Pettenkofer believed in miasmata as the cause of cholera, and installed a remarkable sewage disposal system in Hamburg, which failed completely to reduce the incidence of the disease. Koch applied his knowledge of the cholera vibrio to the problem, installed an adequate water system, and abolished the disease from the city. Koch also made mistakes, and although all of his work on the bacteriology of tuberculosis was correct, some of his epidemiological work was wrong.

Weber found that diphtheria first appeared in Europe in the sixteenth century at about the same time as potatoes, that its incidence increased with increasing use of potatoes, and that the rate was high in cities using many potatoes and low in cities using very few potatoes. He mistakenly concluded that the use of potatoes caused the disease in some way.

Farr's second law that disease increases with increasing density of population is now known to be false, and in reality dwellers in large cities are less smitten by disease than those in rural communities. It is true that some diseases, such, for example, as diphtheria and scarlet fever, are more prevalent in

cities and may be considered as "herd diseases." On the other hand diseases such as malaria and hookworm infestation are mainly rural in distribution.

Dr. Rosenau illustrated some epidemiological methods by telling how an epidemic of hoof and mouth disease was traced to some impure vaccine virus which had been imported from Japan for use in inoculating calves in the preparation of vaccines.

Epidemics are greatly influenced by movements of the population. Because of this mobility the amebic dysentery epidemic of 1933 was spread over a three thousand mile area from its source in Chicago. This epidemic was also the first example of a water-borne epidemic of amebic dysentery, the mass infection of about 1000 cases being due to inadequate plumbing, and the existence of cross connections between the sewage and water systems.

The advent of the airplane, and the rapidity of travel between widely separated areas have raised the serious possibility of initiating widespread epidemics of hitherto comparatively local diseases.

GREATER BOSTON MEDICAL SOCIETY

The next meeting of the Greater Boston Medical Society will be held in the Auditorium of the Beth Israel Hospital, Boston, Mass., Tuesday, January 7, 1936, at 8:15 P.M.

PROGRAM

- 1 The Effect of Intestinal Enzymes on Insulin, Prevention of Digestion of Insulin with Alcohol. Harry Biotner, M.D.
- 2 Visualization of Postgonorrheal Complications. Boris Greenberg, M.D.
- 3 Studies in Gout. B. M. Jacobson, M.D.
- 4 A Method for the Prolongation of the Effect of Medication. H. L. Naterman, M.D.
- 5 Some Effects of Diet Restriction in Patients with Heart Disease. S. Proger, M.D.
- 6 The Quantitative Study of Nasal Obstruction. H. J. Sternstein, M.D.
- 7 The Prevention of Anemia in Pregnancy. M. B. Strauss, M.D.

Physicians and medical students are invited to attend.

H. LINENTHAL, M.D., *President*,
D. B. STEARNS, M.D., *Secretary*

HARVARD MEDICAL SOCIETY

The next meeting of the Harvard Medical Society will be held in the Peter Bent Brigham Hospital Amphitheatre (Shattuck Street Entrance), Tuesday evening, January 14, at 8:15 P.M.

PROGRAM

Presentation of Cases
The Physiology of the Elephant. By Dr. Francis G. Benedict.

Medical students and physicians are cordially invited to attend.

MARSHALL N. FULTON, M.D., *Secretary*

MASSACHUSETTS GENERAL HOSPITAL

A Clinical Meeting of the Staff of the Childrens Medical Service will be held in the Ethor Domo on Friday January 3 at 12 noon Dr Tofft will preside

WILLIAM HARVEY SOCIETY

The next meeting of the William Harvey Society will be held Friday January 10 in the Auditorium of the Beth Israel Hospital Boston at 8 00 P.M.

PROGRAM

Speaker Dr H. Honston Morrill Instructor in Neuropathology Harvard Medical School
Subject Syphilis of the Nervous System.
Chairman Dr Abraham Myerson Professor of Neurology Tufts College Medical School.

THE EXECUTIVE BOARD OF THE CATHOLIC HOSPITAL ASSOCIATION

The Officers and Executive Board of the Catholic Hospital Association of the United States and Canada announce that the Twenty-First Annual Convention of the Association is to be held at the Fifth Regiment Armory Baltimore Maryland, June 15 to 19 1936 under the patronage of His Excellency The Most Reverend Michael J. Curley Archbishop of Baltimore.

BOOK REVIEWS

New Pathways for Children with Cerebral Palsy
Gladys Gage Rogers and Leah C Thomas 167 pp
New York The Macmillan Company \$2 50

In this small book a new note of hope is sounded for children disabled by the various forms of cerebral palsy There is so much more that can be done The authors have not only given us a vision of this but also have outlined a practical and comprehensive program Dr Robert B Osgood, in speaking of the inadequacies of the usual methods of therapy in the introduction to the book states "Equanimity and the banishment of fear and discouragement are immensely more important in rehabilitation than drugs which lessen anxiety, and operations which diminish spasticity" Optimism tempered with common sense radiates from every page For, as the authors state again and again, these patients rarely can be returned to normal physical function. With intelligent guidance, however, all of them can obtain much physical improvement, education in its truest sense and a satisfactory adjustment in the present day world with its modicum of enjoyment and accomplishments This book with its description of games, physical exercises, apparatus, pedagogic methods and lists of books and toys particularly adapted to this group of handicapped children, can be recommended without reservation to physicians, physiotherapists, teachers, and especially parents, who are challenged by the problem of cerebral palsy The authors at their special camp, "Robin Hood's Barn", have to a large part developed the methods described, and in their work have grown in ripe experience and that breadth of soul which this book epitomizes

A Text Book of Fractures and Dislocations Covering their pathology, diagnosis and treatment Kellogg Speed Third Edition, Thoroughly Revised 1000 pp Philadelphia Lea & Febiger \$11 00

The Third Edition of Kellogg Speed's "Fractures and Dislocations" indicates the continued usefulness and popularity of this volume of exactly 1000 pages and over a thousand illustrations The First Edition was published nearly twenty years ago The revision has apparently been thorough and it has been hard for the reviewer to find any of the newer operative or nonoperative methods of proved worth in the treatment of fractures or dislocations (with which he is familiar) which have not been mentioned and usually described The author frequently gives his own opinion as to the efficiency of these methods and the wisdom of their conception. Dr Speed's wide experience and dispassionate attitude make us wish that this personal touch appeared more often The indications for or against open operative attack and the general plan of operative procedures are all sound and well set forth The limits of the book apparently precluded the inclusion of many of the finer details of technique

upon which so much of the complete success of bone and joint surgery must depend. The bibliographical references following each chapter make it possible, however, for the surgeon to acquaint himself with these details. It would be wise for him to acquire this knowledge before he essays to perform for the first time an operation on the bones following a fracture or to open a joint for the purpose of repairing an internal derangement.

The first three chapters comprising about one hundred pages discuss the general principles underlying the treatment of fractures by both closed and open methods and the mechanism and treatment of dislocations. The remaining twenty-one chapters are arranged under anatomical headings.

The amount of the text and illustration in relation to clinical importance and frequency of lesion seems well allotted. The format of the book as to headings and subheadings is excellent; the index is inclusive and the clarity of type and illustrations confer credit on the publishers.

Poliomyelitis. A handbook for physicians and medical students. Based on a study of the 1931 epidemic in New York City. John F. Landou and Lawrence W. Smith. With a section on the orthopedic after-care of the disease by Garry DeN. Hough, Jr. 275 pp. New York: The Macmillan Company. \$3.00.

This handbook based on a study of the 1931 epidemic of poliomyelitis in New York City is primarily a record of the observations of the authors on a large amount of clinical and pathological material comprising approximately 1,000 cases admitted to the Willard Parker Hospital with thirty-one autopsies together with an analysis of some 1,400 additional cases in other communicable disease hospitals.

The volume contains the usual historical review giving the landmarks in the development of our present clinical concept of the disease with bibliographical references. The chapter on etiology and pathogenesis is perhaps too largely devoted to earlier theories and beliefs which have not materialized. The pathological and clinical sections are the best portions of the book. They include comprehensive descriptions of material from the cases studied with original observations. The restriction of the investigations to the single outbreak dothless accounts for the limitations of the chapter on epidemiology. It does not appear particularly useful to devote a separate chapter to nomenclature and classification. The symptomatology is well written and supported by numerous individual case histories which clearly portray the disease especially in its early stages. One cannot but feel that the authors' views on prophylaxis and specific treatment are based to a considerable extent on material which is hardly ready to be incorporated in a handbook. The book ends with a suitable outline of the essentials in the after care of the disease.

Diseases of the Thyroid Gland. Arthur E. Hertzler. Third Edition. Entirely Rewritten. 348 pp. St. Louis: The C. V. Mosby Company. \$7.50.

As stated by the author this book represents the expression of an individual opinion and experience. One who is interested in goitre cannot always agree with Dr. Hertzler in some of his conclusions. It is not fair to say, however, that these conclusions have been arrived at after a large personal experience, in close contact with the cases both before and after operation and a laboratory study of the material. Dr. Hertzler has written profusely on the subject of thyroid disease and has interested himself particularly from the histological and pathological viewpoint.

The book is written in simple English. All phases of goitre and the complications of thyroid disease are considered. A section is included on the hospital management of goitre patients and a chapter on the technique of the operation upon the thyroid gland is included. The illustrations are good and anyone who is interested in the subject of goitre will find the perusal of this book practicable.

Id Livat Again. E. J. O'Meara. 324 pp. Philadelphia: J. B. Lippincott Company. \$2.50.

O'Meara has given us in his memoir a vivid story of the life of an officer in the Indian Medical Service. An old Guy's man he fortunately retained his first pictures of India and his ability to put them on paper. To those familiar with Baden Powell, Curzon and Yongehusband much of the content will have a familiar ring. One can not conclude that after years of ardent service he is certainly one of those fortunate persons who have found life something to be enjoyed rather than simply endured.

Living Along with Heart Disease. Louis Levin. 126 pp. New York: The Macmillan Company. \$1.50.

This short volume is one of the best books written for the lay public that has appeared in recent years. There are many physicians, including the reviewer who doubted the value of the wave of popularization of medical knowledge that has swept over our country. However, one cannot have much doubt about the merits of this treatise for general lay consumption. In fact it can be profitably read by most practitioners. Although the point of view expressed is an optimistic one, the subject matter is treated in a most interesting and truthful fashion. There are very few patients with heart disease who could be harmed by reading this book, and many to whom it would be very profitable. The style of the book has an unusual charm which is possessed by too few of our current medical writers. It outlines in simple form and in interesting language the various problems concerning heart disease. This is done so that the average reader can understand its full significance. It can be highly recommended to both the lay public and the medical profession.

Transactions of the American Gynecological Society Edited by Otto H. Schwarz Volume 59 for the Year 1934 St. Louis C V Mosby Company

This volume of the Transactions of the American Gynecological Society is a collection of all the papers presented at the regular meeting for the year 1934. As would be expected these transactions present a cross section of the best American achievements in the fields of gynecology and obstetrics. The reading of such a collection of papers each year would repay any physician interested in either of these fields.

Medical Practitioners in the Diocese of London, Licensed under the Acts of Henry VIII, C II An Annotated List 1529-1725 J Harvey Bloom and R. Rintson James 98 pp Cambridge The University Press \$1.75

This is an annotated list of the physicians and surgeons licensed as medical practitioners in England by the various bishops of London under an Act of Parliament in the reign of Henry VIII. By this act bishops were empowered to license practitioners after recommendation by three qualified medical men, and examination. Lists of those so registered between 1529 and 1725 are given. In many cases there are brief notes about the individual compiled from well known sources. These lists are valuable as a matter of record and should prove most useful for reference. As an appendix, various forms of certificates used are given and there is a list of the bishops during the period of these registrations. The little book is carefully indexed and finely printed.

Many of the names listed are of well known physicians and surgeons. William Clowes, William Gale, John Fryer, William Cheselden, John Choke, a chemist and a notorious quack, Thomas Saffold, another well known charlatan, and names of lesser importance.

In general, the system of licensing seems to have been efficient. With few exceptions, only those men who had had a long apprenticeship were recognized. The certificates of competency were often signed by important individuals, among whom may be mentioned Sir Hans Sloane and John Evelyn, the diarist.

Clinical Tuberculosis Edited by Benjamin Goldberg Volumes I and II M19 pp Philadelphia F A Davis Company \$22.00 net.

This work which the reviewer believes well merits the adjective "monumental" consists of two large volumes, the total weight of which is over eight pounds, with nearly 2,000 pages replete with many illustrations, descriptive diagrams, tables, cuts, etc., and a thirty-eight page index. The list of contributors contains many names with whom the reviewer does not happen to be familiar but others representing the best that there is in the field of tuberculosis. Among these might be mentioned Drolet,

Alexius Forster, the late Carl Hedblom, Ralph Matson and the late Ray Matson, Edgar Mayer, George Ornstein and others.

In the first volume, which consists of twenty-two chapters, is a most important contribution by Godias Drolet on the "Epidemiology of Tuberculosis," and another, "The Pathologic Physiology of the Tuberculous Lung" by Pol N Coryllos which is divided into five sections with a particularly valuable one on intrapleural pressures and their effects on the tuberculous lung, which subject is all important in pneumothorax work. Ornstein and Ulmar discuss the physical diagnosis of tuberculosis and its classification in three chapters, Hollis Potter continues on the x-ray findings and Dr Goldberg himself its differential diagnosis, prognosis, prophylaxis, home treatment, treatment by rest, exercise and occupation, diet, medicinal, symptomatic and tuberculin therapy in separate chapters. Edgar Mayer discusses the salt restricted dietaries in tuberculosis and Matson takes up pneumolysis and with his brother, Ray, oleothorax and other operations.

In the second volume, containing twenty six chapters and an index, Hedblom discusses the extra pleural thoracoplasty and Dr Mayer, as is to be expected, takes up the question of sunlight treatment. Alexius Forster of Colorado Springs writes on the subject of climatotherapy. Tuberculosis of other organs and parts of the body is taken up by authoritative writers on the subject. The final and particularly important chapter in the second volume is the one on "The Psychopathology of the Tuberculous" by Clarence Neymann.

This work of Dr Goldberg's contains almost too much information to be of value for students and general practitioners, but it certainly should be on the shelves of all sanatorium libraries and will be invaluable for specialists and students in this particular subject. It is a distinct and worthy contribution to the already enormous literature on tuberculosis.

Diseases of the Nervous System A text book of neurology and psychiatry Smith Ely Jelliffe and William A White Sixth Edition, Thoroughly Revised 1175 pp Philadelphia Lea & Febiger \$9.50

This well known textbook, considered by the reviewer to be the most complete book of its kind current in neurological literature, has been revised for a new edition, six years after the previous issue. The bulk of the book has not been increased, in spite of many additions, due to a clever device of making each page somewhat longer, so that there is more material in an equal number of pages. New methods of examination have been added and there are many changes in the chapters on the vegetative nervous system and the endocrinopathies. This book, which has been strongly endorsed by the medical profession in the past, should be welcome in its new dress.

BLOOD IODINE STUDIES IN RELATION TO THYROID DISEASE*

Basic Concept Of The Relation Of Iodine To The Thyroid Gland, An Iodine Tolerance Test

BY H. J. PERKIN, D.S.,† FRANK H. LAHEY, M.D.† AND RICHARD B. CATTELL, M.D.†

PART I

INTRODUCTION

IF some of the fundamental facts regarding thyroid secretion are discussed before the preliminary report of our experiences with blood iodine determinations and the iodine tolerance tests are recorded by H. J. Perkin, it will make it more readily possible for readers who have not been particularly interested in thyroid conditions to comprehend the remarks about blood iodine.

We have known now for a great many years that the secretion and secreting activity of the thyroid gland are intimately linked with iodine that during its stages of overactivity the thyroid gland is in a state of hyperplasia and that during that stage there is an abnormally low content of iodine within the thyroid gland itself (Marine and Lenhart¹, Cattell²).

It is possible now to extract by hydrolysis and precipitation a crystalline substance known as thyroxine (Kendall³) which has all of the physiological properties of thyroid extract. This active principle of the thyroid contains sixty five per cent iodine and it is now quite generally accepted that the effectiveness of thyroid material to be employed therapeutically is proportional to its iodine content. It is, therefore, evident that the iodine content of the thyroid is related to the activity of that gland and is a probable indication as to whether the thyroid is storing its active principle or is pouring it out into the blood stream to stimulate the rapid heart action and increased metabolism observed in hyperthyroidism.

To understand the reasons why blood iodine is usually elevated in patients with excessive thyroid secretion (hyperthyroidism) and to grasp the basis of the blood iodine tolerance test as developed by Mr. Perkin, it is necessary to review some of the changes which take place in the thyroid during its secreting activity in

hyperthyroidism (hyperplasia), the histologic and chemical changes which take place in the gland as the result of the administration of iodine (Lugol's solution) at this time (involution) and the relation of the histology in the normal gland to the iodine content.

The glandular unit of thyroid activity is a ring of epithelial cells surrounding an acinus overfilled (involution), moderately filled (normal) or scantily filled (hyperplastic—hyperthyroidism) with what probably represents the vehicle (colloid) containing the active principle of the thyroid secretion.

When the thyroid gland is secreting normally, it appears as shown in Figure 1. The epithe-

Diagrams 1, 2, 3
a. Papillary Projection

FIGURE 1. Diagrammatic representation of the normal thyroid unit. The acinus filled with a moderate amount of colloid and lined with normal cuboidal epithelium.

FIGURE 2. Diagrammatic representation of the thyroid unit in hyperthyroidism. Note the small amount of colloid within the acinus, the papillary projection (a) into the acinus and the columnar type of epithelium lining the acinus.

FIGURE 3. Diagrammatic representation of the thyroid unit of a patient with hyperthyroidism after treatment with iodine. Note the change designated as involution, a large amount of colloid in the acinus, dilatation of the acinus and flat inactive epithelium lining the acinus.

lium lining the acinus will be flat cuboidal in character. There will be a moderate amount of colloid material within the acinus and the iodine content of the gland in terms of milligrams of iodine per gram of dried gland will be found to be within normal limits (Approximately 20 milligrams).

When a patient develops primary hyperthyroidism or exophthalmic goitre, then certain histologic and chemical changes take place within the thyroid gland and the epithelium surrounding the acinus becomes high columnar in char-

From the Lahey Clinic; The Baker Memorial Clinic of the New England Deaconess Hospital, and The New England Baptist Hospital.

*Perkin, H. J.—B.S. Research Fellow in Biochemistry, Lahey Clinic. Lahey, Frank H.—M.D. Director, Lahey Clinic. Surgeon-in-Chief, New England Baptist Hospital. Cattell, Richard B.—A.B. M.D. Surgeon, Lahey Clinic, New England Deaconess Hospital and New England Baptist Hospital. For records and addresses of authors see "This Week's Issue," page 22.

aceti, its acinar margin becomes crinkled and projects into the acinus in a papillary-like form and the amount of colloid in the acinus is impressively diminished, as shown in figure 2

During this stage of hyperplasia and glandular activity, the iodine content of the thyroid drops strikingly in terms of milligrams of iodine per gram of dried gland until it is often as low as 0.4 of a milligram per gram of dried gland (Marine and Lenhart¹, Cattell²). It is during the stage of excessive and abnormal thyroid activity that the thyroid gland discharges its contained iodine and it is in this state of thyroid abnormality that high values of iodine are found in the blood stream

Since the iodine fraction of thyroxine is necessary to make it active since the amount of colloid in the thyroid in the patient with hyperthyroidism is strikingly diminished, since the blood iodine in this state is found elevated and the iodine content of the thyroid low, one can, of course, theoretically assume that the increase in blood iodine is evidence of an increase in circulating thyroxine. That this is possibly so is made further probable by the information presented by Mr. Perkin in chart 3 in which the drop in blood iodine value, similar to the drops in metabolisms are shown before operation, three months after operation and six months after operation

If one now administers iodine (Lugol's solution) to the patient with excessive thyroid activity (hyperthyroidism) at this time very definite changes take place in the patient clinically, in the blood iodine, in the histologic appearances (involution) of the gland and in the iodine storage in the thyroid gland as shown in figure 3. The epithelial cells lining the acinus are flattened and within the acinus there accumulates a large amount of colloid material (involution). The blood iodine drops and the amount of iodine within the thyroid gland rises sharply until it may be as high as 80 milligrams of iodine per gram of dried gland. During this stage of involution there are, usually in 90 per cent of the cases (Cattell) clinical evidences of relief as indicated by a drop in basal metabolism and pulse rate and a gain in weight. Having operated upon several thousands of thyroid glands during this stage of involution, we know also that there are gross changes in the gland at the time which as the result of the accumulation of such large amounts of colloid in the acinus are quite obvious to anyone experienced with thyroid surgery. The gland becomes strikingly firm the vascular and lymph channels between the lobules as the result of acinar distention become for a time obstructed (Marine and Lenhart¹) the vascularity of the gland diminishes and its diffusion of thyroxine through the lymphatics because of their obstruction also

limited. This plus the possible mechanical effects of the pressure of excess colloid in the distended acinus upon the epithelial cells lining the acinus (Marine and Lenhart¹) is the probable reason why involution as brought about by Lugol's solution or any other form of iodine results in such a prompt but temporary improvement in the clinical symptoms in patients with hyperthyroidism.

We have for years appreciated and maintained that the effects of iodine upon patients with hyperthyroidism were not to cure them of hyperthyroidism but to bring about a temporary improvement during which time surgery can be more safely carried out.

It is probable from the clinical course of patients with hyperthyroidism on iodine that the thyroid gland adapts itself to the distention of its acinus with colloid, that the temporarily restricted blood supply partly resumes its abnormal amount and that temporarily obstructed lymph channels as they adapt themselves to the new conditions are reopened (Marine and Lenhart¹). This results then in a return of the severe symptoms of hyperthyroidism, increasing tachycardia, weight loss and increases in basal metabolism. Iodine becomes less effective in maintaining this clinical remission and the patient is then, so-called iodine fast. The period of improvement during which the operation could have been more safely done has been lost, and it is not possible again to get the same striking iodine improvement in the patients even though they be taken off iodine for several weeks and put back on it again after this interval.

It is for the above reasons that we have always urged upon physicians that if their patients are not to be operated upon, they may give them all the iodine they choose, but if they are to be operated upon that they be sent to the surgeon not having had iodine, in order that he may give it to them, observe the period of maximum improvement and operate upon them thus with greater safety at that time.

To epitomize then our knowledge of iodine in hyperthyroidism exclusive of blood iodine. When we have hyperthyroidism with hyperplasia there is a low iodine content within the thyroid gland. At this time the gland leaks its iodine into the blood stream and is unable to store it. This hyperplastic gland of hyperthyroidism has, however, a tremendous thirst or affinity for iodine and if iodine, usually Lugol's solution in any form be given at this time, it will promptly (literally within an hour or an hour and a half, see iodine tolerance charts) be accepted and stored in the gland as shown by the iodine tolerance curve. Following this within four to ten days, there will be a marked change in the thyroid gland (involution) which will result in a temporary improvement in the clinical picture of hyperthyroidism.

PART II

Biochemical investigation has done much to elucidate more clearly some of the physiological factors associated with thyroid disease. Of recent years, improved methods of quantitative blood iodine estimation have more firmly established the presence of an abnormal iodine metabolism associated with increased physiological activity of the thyroid gland. In clinical hyperthyroidism, there usually exists a de-

crease in the iodine of the thyroid gland concomitant with an increase of iodine in the blood and urine. In order to place the relationship of the blood iodine to thyroid disease on a firmer basis the present study was undertaken.

The group of cases studied to date and recorded herewith, number four hundred and sixty-six. This group included blood iodine estimations on one hundred and twelve normal individuals, one hundred and eleven patients with adenomatous goitre and no clinical toxicity, one hundred and seventy-four pa-

tients with primary hyperthyroidism, thirty-five patients with adenomatous goitre and secondary hyperthyroidism and thirty-two patients checked three and in some instances, six months following subtotal thyroidectomy for hyperthyroidism. Patients having other conditions known to influence the blood iodine level such as gallbladder disease, elevated temperature or treatment with iodides for conditions other than thyroid disease, were not included. All other cases were included. Except in the group of

CHART 1

The blood iodine range on one normal individuals is

18.3 gamma per cent with an average of 6.6 gamma per cent. One gamma is synonymous with one microgram and is equivalent to 0.01 milligrams. Seven normal individuals had a blood iodine concentration in excess of ten gamma per cent. Two of these individuals were surgeons whose frequent contact with iodine might account for the increased blood concentration. One individual was of the nervous Latin race and temperament and consistently

patients were nontoxic, the surgically removed thyroid showed secondary hyperplasia. In the remaining four cases there was no evidence of thyroid toxicity (See chart 1).

In one hundred and seventy-four cases of primary hyperthyroidism, the blood iodine range varied from 2.0 to 14.9 gamma per cent with an average of 21.0 gamma per cent. Of this group fifty-two cases or 30 per cent had a normal blood iodine in the presence of clinical

CHART 2

showed an elevated blood iodine concentration. The elevation of blood iodine in the other four cases could not be explained. Irrespective of this group we have tentatively adopted ten gamma per cent as the upper normal limit by our methods (See chart 1).

The blood iodine of one hundred and eleven clinically nontoxic adenomatous goitrous individuals was found to vary from 2.0 to 12.8 gamma per cent with an average of 6.6 gamma per cent. Of this group, there were eight cases in which a blood iodine concentration of 10 gamma per cent was exceeded. In four of these eight cases, although clinically the

and microscopical evidence of hyperthyroidism. Six of these fifty-two patients were in iodine remission but had no iodine therapy for at least one week prior to the test. While we are unable to satisfy ourselves as to the reason why 70 per cent of this entire group of cases should present an elevated blood iodine and 30 per cent a normal blood iodine, there are certain features of this latter group which have attracted our attention. In this 30 per cent group fall the more severe cases of the entire group in that they usually did not appear to respond so effectively to iodine therapy preoperatively, and as a result, two-stage operative procedures were

more often necessary. Such operative procedures were required in nineteen cases or 36.5 per cent of this latter group while in all hyperthyroid patients passing through the Clinic, 22 per cent require two-stage operations. Primary hyperplasia with irregular involution of the excised thyroid was a consistent finding in patients from this group.

The blood iodine range of thirty-five individuals having adenomatous goitre associated with clinical toxicity varied from 3.6 to 66.5

Although three months after operation, the blood iodine in seven patients was still elevated above the upper normal limit, it was markedly decreased, relative to the preoperative blood iodine. Six patients had an elevated blood iodine three months postoperatively and four of these six cases had clinical evidence of persistent hyperthyroidism. (Dotted lines—charts 2 and 3.) All the cases of persistent hyperthyroidism were observed three months after their first operation, before which they had

CHART 2

Straight lines show B. M. R. values of patients clinically improved. Dotted lines show B. M. R. values of patients with clinical recurrence. Please note how drop in blood iodine in chart 2 parallels drop in basal metabolism in this chart.

gamma per cent with an average of 20.2 gamma per cent (chart 1). Of this group eight cases or 23 per cent had a normal blood iodine in the presence of clinical hyperthyroidism. Four of these eight cases were serious enough to warrant two-stage operative procedures.

In twenty-six patients who had subtotal thyroidectomy for hyperthyroidism, a striking decrease in blood iodine concentration, paralleling the decrease in basal metabolic rate, was found three months postoperatively in those cases where clinical improvement was present. The blood iodine relationship is shown graphically in chart 2 and the corresponding basal metabolic rates of the same patients in chart 3.

normal blood iodines. In view of this, we shall be interested to observe in further studies whether the tendency toward recurrence is consistently greater in those cases of clinical hyperthyroidism with a normal blood iodine.

A further decrease in blood iodine concentration was found six months postoperatively in seven cases, two of which had been followed since the preoperative period. One case (dotted line 3-6 months P. O.) had clinical evidence of recurrent hyperthyroidism at six months which was confirmed at the nine months checkup. The blood iodine (dotted line) was elevated at the six months' period preceding the patients' clinical manifestations of hyperthyroidism but de

creased to a normal blood level at the nine months' period when the presence of hyperthyroidism was evident. Thus one case reassures us of the real probability of a normal blood iodine in the presence of clinical hyperthyroidism and lends credence to the results of the hyperthyroid group shown in chart 1 with a normal blood iodine.

The presence of excess amounts of iodine in the blood of individuals with clinical hyperthyroidism has been reported by Dodds⁶ and others^{6, 7}. No reference, however, has been made to the possible presence of a normal blood iodine in hyperthyroid individuals except by Turner⁸ and Perkin⁹ who independently reported that 20-30 per cent of the cases studied by them had a normal blood iodine. This study confirms our former observations. These hyperthyroid patients with a normal blood iodine, as previously stated, did not appear to respond so effectively to preoperative Lugol's therapy, two stage operative procedures were more frequently employed, and as suggested by the post-operative observations, the tendency toward persistent hyperthyroidism was greater.

We offer two possible explanations, based on clinical observations for the presence of a normal blood iodine in hyperthyroidism.

(a) In long-standing cases of hyperthyroidism which have not had iodine therapy, the thyroid gland becomes deficient in iodine as indicated histologically by the marked reduction of colloid material and chemically by iodine analysis³. In the earlier stages of the disease there is an excess of iodine in the blood⁶ and urine¹⁰, the urinary iodine being a direct loss to the body. It is reasonable to assume therefore, that a time would be arrived at when the thyroid could no longer sustain the excess iodine of the blood and urine and these values would then fall to a normal or even subnormal level. In support of this viewpoint is the fact that in the toxic adenomatous group, who had not had iodine therapy, there were no cases with a normal blood iodine. On such a hypothesis the size of the thyroid gland at the initiation of hyperactivity would prolong the time that an elevated blood iodine could be maintained.

(b) Study of the remaining fifty cases of hyperthyroidism with a normal blood iodine revealed that they had all received repeated iodine treatment prior to hospitalization. The greater number of cases receiving therapeutic x-ray treatment for hyperthyroidism were also within this group. The increased severity of this clinical state has been pointed out above. This confirms the observation made by others^{11, 12} that intermittent iodine therapy in hyperthyroidism may be a very unwise procedure.

The blood iodine studies on the group of patients before and after subtotal thyroidectomy for hyperthyroidism with clinical improvement

in most cases and recurrence in a few, definitely illustrate, we believe, a relationship between clinical hyperthyroidism and the blood iodine level. It is not to be inferred that we believe iodine to be the sole factor in the etiology of thyroid disease but we do feel that it is a primary one.

PART III

AN IODINE TOLERANCE TEST

In view of the findings that single blood iodine estimations were not always capable of differentiating toxic and nontoxic goitre, we have, by frequent blood iodine estimations following the ingestion of a fixed dose of Lugol's solution, established the blood iodine curve in a given time period and called this the blood iodine tolerance curve. It is hoped that this test will be an objective criterion by which the presence of hyperplasia in the thyroid gland may be predicted in any particular patient.

The technique of the test may be reviewed briefly as follows. 10 cc of blood is withdrawn from the patient, following which a known amount of iodine as Lugol's solution (37.5 milligrams iodine used at present) in milk is given orally. At one-half hour, one hour, one and one-half hours and at two and one-half hour periods, two cc blood samples are taken. The morning of the test, no breakfast is given. All other meals are allowed. Iodine estimations are carried out on the separate samples of blood. The blood iodine curve with respect to time is graphically plotted.

The difference in blood iodine curves between the normal nontoxic adenomatous and hyperthyroid individual is illustrated in chart 4.

From the above chart it may be seen that the blood iodine curve does not rise to such a high level in the hyperthyroid individual as in the normal or nontoxic goitrous patient. It is reasonable to assume that a hypothetical line exists differentiating the normal and nontoxic goitre whose blood iodine curve rises above and the individual with hyperthyroidism whose blood iodine curve falls below this line. This hypothetical line is tentatively placed at 80 gamma per cent in the above chart. Obviously, the height of the differentiating line would be dependent on the amount of iodine ingested and the differentiating principles obliterated when very large or very small doses of iodine were given. Thus an optimum dosage of iodine exists whereby the greatest variation between the normal and abnormal is obtained. Our work to date indicates that this optimum dosage varies in different geographical regions since 75 milligrams of iodine was differentiating at Toronto, Canada⁹ while 37.5 milligrams appears to be closer to the optimum in this area. The relatively larger number of cases with nodular goitre in the Toronto area in contrast to the greater proportion of primary hyperthyroid

eases seen at the Lahey Clinic may account for this difference or there may be other variable factors which at present are not clear.

It would appear from our work to date that the differentiating principle in these tests

individuals following the injection of 1300 gamma of iodine as potassium iodide. The blood iodine curves of four typical cases with thyroid enlargement are shown in chart 5. The level to which the blood iodine rises dependent upon

may be attributed to the degree of physiological and pathological activity of the thyroid gland. The work of Elmer^{12, 14} lends support to such a hypothesis by his method of tracing the blood iodine curve and urinary excretion of iodine in myxedematous, normal and hyperthyroid indi-

viduals following the injection of 1300 gamma of iodine as potassium iodide. The blood iodine curves of four typical cases with thyroid enlargement are shown in chart 5. The level to which the blood iodine rises dependent upon

These iodine tolerance curves are, however, subject to variation. At present they must be interpreted in the light of the clinical picture as a whole. Further study will clarify the irregularities that occur and make their correct interpretation more possible. It is hoped that the iodine tolerance test may prove diagnostically valuable in a manner similar to that which sugar tolerance curves have in diabetes.

SUMMARY

- 1 Some of the fundamental facts regarding iodine and thyroid secretion are discussed.
- 2 Blood iodine ranges have been established on normals, nontoxic adenomatous goitrous and hyperthyroid individuals in the New England area.
- 3 The presence of an elevated blood iodine in all cases of clinical hyperthyroidism is not absolute. Twenty-nine per cent had a normal blood iodine.
- 4 An elevated blood iodine in hyperthyroidism appears to be compensatory and desirable, if not present it at least suggests an intense state of thyroid intoxication.
- 5 Following subtotal thyroidectomy for hyperthyroidism, when clinical improvement is present, the blood iodine is decreased in relation to the preoperative blood iodine, and elevated when persistent or recurrent toxicity is present, although in

extreme cases, it may remain unaffected by the surgical procedure.

- 6 An iodine tolerance test is described which may prove to be a valuable asset in establishing a diagnosis of hyperthyroidism.

MORTALITY FACTORS IN ACUTE APPENDICITIS*

Study of 1,000 Cases

BY EDWARD D. LEONARD, M.D., † AND SIDNEY DEROW, M.D. †

ONE thousand consecutive cases of acute appendicitis operated upon at the Newton Hospital have been studied in an effort to determine the possible factors influencing the mortality rate. Fourteen hundred and two cases (1923-1933) reported as clinical acute appendicitis were reviewed. Four hundred and two of this number, although presenting clinical pictures of acute appendicitis, were not included in this series, because of the pathological reports which did not confirm this diagnosis. The remaining 1,000 cases were positive acute appendices and their complications. There were forty-seven deaths in this group giving a mortality rate of 4.7 per cent.

The factors which appear to affect the mortality rate are individually discussed below.

Sex. Five hundred and forty of the patients were males and four hundred and sixty were fe-

males. The former group accounted for twenty-five deaths (4.6 per cent) and the latter group for twenty-two deaths (4.8 per cent). The disease was more prevalent in males, but the difference in the mortality rates between the two was negligible.

Age. As the accompanying graph (chart 1) illustrates, the condition is most common in the second and third decades of life (57 per cent of all the cases fall in this period). Fortunately, the mortality rate is lowest (2 per cent) in these cases (see chart 2). The death rate during the first five years of life is relatively high (8 per cent). Beginning with the end of the fourth decade there is a steady rise in the mortality rate. The percentage of perforated cases (chart 3) in the different age groups runs a course parallel to the death rate. Seventy-four per cent of all the patients under five years of age in this series showed free pus at the time of operation. Fifty per cent of the cases over fifty years of age had peritonitis or abscess formation. The above findings emphasize the importance of early diagnosis and operation in these age groups.

*From the Surgical Service of the Newton Hospital, Newton, Massachusetts.

†Leonard, Edward D.—A.B., M.D., Surgeon in Chief, Newton Hospital, Newton. Derow, Sidney—M.D., Junior Surgeon, Newton Hospital, Newton. For records and addresses of authors see "This Week's Issue" page 83.

Duration Charts 4 and 5 illustrate vividly the relationship of duration of the disease before operation to the mortality. Eighty-four cases

the mortality rate after operation increases steadily reaching a peak (13.9 per cent) on the fourth and fifth days after the onset of symp-

of acute appendicitis five of which had peritonitis, were operated upon within ten hours after the onset of the symptoms without a single death. Following this relatively safe period,

Operation done after this period shows a slight but definite drop in the mortality rate. The death rate on the fourth and fifth days without doubt placed that group of

CHART 4 Duration and Incidence

CHART 5 Duration and Mortality

CHART 6 Duration and Perforation

cases which are "too late for early surgery and too early for late surgery" Findings similar to these have been discussed by Walker, Collier and others. The percentage of cases of perforation varies directly with the duration of the symptoms before operation (chart 6)

CATHARSIS

	All Cases (1,000)	Perforated Cases (274)	Deaths (47)
History of Catharsis	103	50	7
Per cent of Patients who took Cathartic	10.3	18	15

Forty-eight per cent of all the patients who gave a history of catharsis had ruptured appendices at operation. Fifteen per cent of all the deaths were patients who took cathartics. These figures show another strong influence on the death rate before the patient actually comes to operation. It is therefore apparent that operation in itself will never lower the death rate sufficiently until the laity is taught not to treat all "stomach aches" with cathartics and waiting for symptoms to cease.

PREVIOUS ATTACKS

	All Cases (1,000)	Perforated Cases (274)	Deaths (47)
History of Previous Attacks	234	42	5
Per cent of Patients having Previous Attacks	23.4	15	10.6

Conclusions have not been drawn from these figures because many past histories were brief. However, they do stimulate interest in future studies and show that one attack of appendicitis does not immunize against future attacks. A number of patients who died undoubtedly would be alive now if the appendix had been removed during the interval rather than to have waited for another acute attack. The quality of surgical service undoubtedly has a definite relation to mortality statistics in this disease.

ANESTHESIA

	No of Cases	Deaths	Per Cent Deaths
Gas Oxygen Ether	961	40	4.1
Gas Oxygen	7	1	14.2
Spinal	25	5	20
Local	7	1	14.2

Throughout this entire series ether was the anesthetic of choice. Gas oxygen and local anesthetics were used in cases gravely ill at time of operation. Spinal anesthesia was employed in some elderly patients with pulmonary compli-

cations There were two definite spinal deaths on the operating table. Gas oxygen ether anaesthesia in itself was not the cause of any deaths in this series

OPERATIVE PROCEDURES

a Incision

Type of Incision	No of Cases	Deaths	Per Cent
Right Rectus	900	41	4.5
McBurney	65	2	3.0
Midline	84	4	11.9

One case presented as a strangulated hernia and the operation included the removal of an acute appendix through a right inguinal incision. The inadvisability of midline incisions for this condition is apparent, they were used in this series in a few cases presenting a question of diagnosis in a female. Although McBurney incisions were used in only sixty-five cases the low death rate is worthy of note and future study. Reid has reported interesting results with the use of this incision. (At present the Service is running a series of McBurney incisions since a comparison between the results of right rectus and McBurney incisions will be of instructive interest.)

b Drainage

Four hundred and eighty-six cases were drained and forty-three of the deaths were in this group. In recent years drainage in early spreading peritonitis has been instituted more infrequently than in the past. Many surgeons strongly advise against drainage in these early cases. In this series drains were used rather often. Except for possibly a more prolonged stay in the hospital we do not feel that drainage in itself contributes very strongly to immediate mortality in acute appendicitis. It is however, an important factor in postoperative late complications such as hernia and intestinal obstruction. Various writers have proved the inadequacy of drainage and we drain at present fewer cases than we did in the past. It is difficult to forget the old dictum "When in doubt, drain."

c Disposition of Appendix Stump

The stump was inverted in 582 cases. No relation between inversion of the stump and mortality could be ascertained.

The great majority of drainage cases showed peritonitis or abscess at operation. Appendectomy with appendicostomy or cecostomy was done in seven cases with no deaths, although this is a small collection of cases, it is of significance. Some writers advise routine appendicostomy or cecostomy in all cases of spreading peritonitis.

d Type of Operation

	Cases	Deaths
Appendectomy without Drainage	512	2
Appendectomy with Drainage	436	39
Incision and Drainage		
Appendix not removed	40	2
Appendectomy with Drainage and Ileostomy	1	0
Appendectomy with Drainage and Cecostomy	6	0
Appendectomy with Drainage and Appendicostomy	1	0
Incision and Drainage and Ileostomy (Both patients moribund)	2	2

COMPLICATIONS OF ACUTE APPENDICITIS FOUND AT OPERATION

Complication	Patients	Deaths	Per Cent
General Peritonitis	138	25	19
Local Peritonitis	48	4	8
Appendix Abscess	82	5	6
Pelvic Abscess	4	1	25
Pelvic Peritonitis	8	1	12
Total	274	36	13.1

The death rate in acute nonruptured appendicitis was 1.5 per cent.

The case listed as a death from Pelvic Abscess was a woman seven months pregnant who came into the hospital ten days after onset of symptoms. She was moribund and had intestinal obstruction. Her prognosis was hopeless from the beginning.

CONCLUSIONS

Mortality, in the average cases of acute appendicitis, is not the result of a single factor, but is due to a combination of factors. Of prime

significance in the causes of mortality are the following

- 1 Age of the patient
- 2 Duration of Symptoms before operation
- 3 Catharsis
- 4 Type of Anesthesia
- 5 Type of Operation
- 6 Postoperative Care
- 7 General Condition of patient before operation
- 8 Skill and Judgment of each individual Surgeon

SYMPTOMATIC PSYCHOSES WITH BROMIDE INTOXICATION*

Their Occurrence in Southern New England

BY PAUL WILLIAM PREU, M D, † JOHN ROMANO, M D † AND WARREN T BROWN, M D †

INTRODUCTION

CASES of bromide intoxication with symptomatic psychosis have been reported from Maryland by Wuth¹ Diethelm², and Wainwright³ a series from Colorado has been described by Wagner and Bunbury⁴, cases from Texas have been described by Harris and Hauser⁵ from Pennsylvania by Levin⁶, and from North Carolina by Craven⁷ In spite of the wide distribution and the obviously increasing recognition of this condition, cases have been seen

with such frequency in New Haven that it seems justifiable to call to the attention of the physicians of New England certain dangers in the use of bromide, and to point out the specific methods for the diagnosis and treatment of bromidism

Credit should be given to Wuth for awakening interest in bromide intoxication in this country He devised a simple laboratory method for the quantitative estimation of bromide in the blood, which will be described below Since the publication of his paper in 1927, knowledge of psychoses with bromide intoxication has been extended by other investigators, until at the present time this group of mental disorders is one of the best understood psychiatric conditions

*From the Department of Psychiatry Yale University School of Medicine

†Preu Paul W—BS MD Chief of Clinic Psychiatric Clinic, New Haven (Conn) Hospital Romano John—BS MD House Officer and Fellow in Psychiatry Colorado Psychopathic Hospital, Denver Colorado Brown Warren T—MD Instructor in Psychiatry Yale University School of Medicine For records and addresses of authors see "This Week's Issue" page 83

PHARMACOLOGY

The principal action of bromide is its depressing effect upon the central nervous system. Because of this valuable sedative action it has been extensively employed in the treatment of nervous and mental diseases. Many consider it the most effective drug for the treatment of idiopathic epilepsy. It is a valuable aid in the management of tensional states accompanied by anxiety and insomnia. In suitable cases, if the patient remains under constant medical supervision, the use of bromide is safe. Bromide is readily absorbed from the stomach when given by mouth and appears in the urine within a few minutes after ingestion. The elimination of the drug from the body proceeds slowly, however. Bromide tends to displace chloride in the blood and other body fluids where it may accumulate to such an extent that a state of intoxication is produced. The chloride which is displaced is excreted by the kidney in preference to bromide.⁸ The interchange of chloride and bromide apparently involves equilibrium reactions since the administration of large amounts of chloride accelerates the elimination of bromide. It follows that the danger of intoxication is diminished by a generous chloride intake, and is exaggerated in states of malnutrition, cachexia, and dehydration in which the intake of fluids and chlorides may be limited or the stores of these substances in the body depleted. Impairment of renal function in nephritic and arteriosclerotic conditions may also enhance the risk of intoxication.

SYMPTOMATOLOGY

If the accumulation of bromide in the blood and tissues continues, definite intoxication develops. Several authors recently have described the symptoms of bromide intoxication in detail with special reference to the psychiatric manifestations. Dietheilm, Wainwright,² and Levin,³ have published excellent descriptions of the clinical pictures they observed. The symptomatology will be reviewed here briefly in order to call attention to two points which are of special importance to the internist: first, the delirious or "symptomatic" character of the mental disturbances; and secondly the apparent independence of the psychiatric and dermatologic symptoms of intoxication.

The early symptoms of bromide intoxication are an exaggeration of the therapeutic sedative effect. Definite retardation of thought, speech and action appears together with anorexia, constipation, weakness and drowsiness. This stage of intoxication is seldom dangerous if it is recognized before the appearance of frank psychosis and the symptoms clear up gradually when the administration of bromide is discontinued. If this is not done, however, and the drug continues to accumulate, outspoken psychosis, which may cause serious difficulty,

frequently occurs. Drowsiness and lethargy may be replaced by insomnia and irritable restlessness. The patient refuses food and fluids and may become severely dehydrated. Dry mucous membranes, furred tongue, foul breath, dilated pupils, ataxia and tremulousness are typical symptoms of the more severe states of intoxication. Symptomatic or delirious psychotic manifestations appear.

A disturbance of consciousness, the characteristic feature of symptomatic psychosis,⁴ is manifested by the primary symptoms of delirium: disorientation, fluctuation of the level of awareness and disturbance of memory. These symptoms are directly dependent upon an organic disturbance of cerebral function. On the basis of this organic disturbance of the sensorium, the patient usually develops more elaborate secondary symptoms which are colored by constitutional and personality factors and by his way of experiencing the organic delirium. Delusional trends, hallucinations and emotional disturbances are produced which complicate the clinical picture.

In some cases, for reasons which are not entirely understood, skin lesions appear. The eruption usually is pustular acneiform in type, indistinguishable in appearance and distribution from acne vulgaris. These cutaneous eruptions generally appear only after prolonged administration of bromide⁵, thus differing from the exanthems of drug idiosyncrasy. A preëxisting seborrhoeic tendency is said to predispose to bromide acne. No published studies of blood bromide with reference to the dermatologic lesions have been found, but it has been our experience that extensive skin eruptions may occur with relatively low blood bromide levels. Severe skin eruptions are found in the absence of psychosis, while the skin may be normal in the presence of outspoken mental disturbance. This point demands emphasis because some physicians prefer to wait for the appearance of a skin eruption before making a diagnosis of bromide intoxication. Dependence upon the bromide eruption as a diagnostic aid is one of the chief reasons why symptomatic psychoses due to bromide pass unrecognized. A blood bromide level of 250 mg per cent or higher will account for a delirious psychosis in a patient who is in fairly good physical condition. Stated in another way, severe intoxication will usually be produced by a displacement of more than 30 per cent of the blood chloride by bromide. The delirious condition is due to the presence of bromide, however, not to the deficiency in chloride.

The existence of bromide intoxication is suggested therefore by psychiatric or dermatologic symptoms which may be found alone or in combination.

DIAGNOSIS

Most patients to whom bromide is given are suffering from some neuropsychiatric illness

which causes its own symptoms, so that if bromide delirium is superimposed a very complicated psychiatric picture is produced. If the characteristic symptoms of delirium are recognized, there is usually little difficulty in making the differential diagnosis, for disorientation, clouding of consciousness and memory defects cannot be attributed to a preexisting mild neurologic or psychiatric condition or to a functional psychosis. If the bromide was given to allay the symptoms of an organic mental illness, such as psychosis with cerebral arteriosclerosis or delirium accompanying an infectious disease, the symptoms caused by bromide intoxication are sometimes indistinguishable from the symptoms of the original mental illness. Even in such cases, however, the presence of bromide intoxication may be suspected if there is a sudden exacerbation in the mental disturbance which is not accounted for by a change in the physical condition.

The skin lesions produced by bromide are not specific, but are of some diagnostic importance if a history of the administration of sedatives can be obtained, particularly if the eruption is associated with delirium.

A definite diagnosis of bromide intoxication can be made only by the identification of bromide in the blood or urine. Wuth's modification of the Walter-Hauptmann method is the standard laboratory test for bromide, and is sufficiently accurate for clinical purposes. Since the urine may be free of bromide when the blood bromide is high¹¹, the blood should always be examined. Either whole blood or serum may be used, the serum yielding lower readings, especially at low blood bromide levels. The test may be carried out readily in a small laboratory or physician's office. The blood protein is precipitated by trichloroacetic acid, the mixture is filtered and gold chloride added to the clear filtrate. A reddish brown color develops if bromide is present. The mixture is then compared with a standard in a colorimeter or by means of a colorimeter*. The method is fully described by Wuth¹ and Diethelm². It is well to determine the blood chloride simultaneously

TREATMENT

The treatment of bromide intoxication consists of general supportive measures plus the administration of chloride to eliminate bromide from the tissues.

Since almost all the patients are admitted in a malnourished or dehydrated condition, steps should be taken to insure an adequate intake of food and fluid. It is our practice to give a high caloric soft diet rich in vitamins and a minimum of 4000 cc of fluid a day to severely intoxicated patients. In psychotic cases feeding by gavage is frequently necessary. Repeated

enemas should be given to combat the intestinal sluggishness.

Approximately ten grams of chloride a day should be given in addition to the salt contained in the ordinary diet. Except in emergency, parenteral saline is contraindicated, as Wile¹¹ has shown that the rapid elimination of bromide may cause damage to the kidney.

Chemical sedation is contraindicated and usually ineffective⁷, although drugs are occasionally required to combat extreme excitement and noisiness. Continuous tubs and cold wet sheet packs are the best means of combating insomnia and excitement.

The intoxication can usually be controlled in less than three weeks by the methods described. The underlying illness, for which bromide was given, of course demands its own treatment.

CASE REPORTS

CASE 1 E W, aged fifty three, a single business woman, was admitted on February 12, 1934. Twenty years previously she had experienced a depression with complete recovery. The present illness had begun early in 1933 and had been characterized by increasing depression and agitation. Her family physician had administered an unknown quantity of bromide for several weeks before hospitalization in an attempt to quiet her. For a week before admission she had eaten poorly and had been increasingly drowsy.

On admission the vital signs were normal. There was a diffuse acneiform eruption on the face and chest. The tendon reflexes were hyperactive. The patient was disoriented for time and place, showed fluctuation of the level of awareness and had auditory hallucinations. Her speech was slow, thick, and incoherent.

A soft diet was given, plus 3,000 cc of fluid and eight grams of sodium chloride daily. After ten days the delirium subsided, revealing an agitated tensional depression. No further improvement in her condition occurred, and she was discharged against advice on March 26, 1935.

The serum bromide on February 12, 1934 was 125 mgm per cent (15.5 mM/L*). On February 27, 1934 the serum bromide was not detectable.

Comment Bromide was given in an attempt to manage an agitated depression in the home. A sedative effect was obtained, but the patient could not be fed properly, and within a few weeks became intoxicated.

CASE 2 M M, aged thirty five, a housewife, was admitted on December 21, 1934. Six years previously, following the birth of her first child, she had experienced a depression with complete recovery. A second child had been born in July, 1934, and a few weeks later she had again become retarded, depressed and hypochondriacal. At home, under the care of her family physician, she had eaten poorly and her mental condition had not improved. A suicidal attempt led to her admission to the Psychiatric Clinic.

On admission her physical status was not remarkable. Symptoms of a retarded depression were present, but there was no evidence of a symptomatic psychosis. She was discharged against advice, somewhat improved, on December 30, 1934.

*Manufactured by LaMotte Chemical Company, Baltimore, Md.

*Millimols per liter

At home she became agitated and on January 11, 1935 her family physician began the use of five grams of bromide daily in an attempt to quiet her. On January 13 she had hallucinations of giant Negroes armed with knives and of large dogs about to attack her. She struck at these imaginary enemies with household utensils. Her husband who was with her constantly maintained that she was always correctly oriented during the periods of hallucination.

She was readmitted on January 21, 1935. Her physical status again showed no abnormality. There was no skin eruption. She was returned and depressed but was correctly oriented and displayed no fluctuation of the level of awareness. There was no evidence of hallucinations in any of the sensory fields. When asked to recount her previous hallucinatory experiences she said she had not been confused but had been frightened by the sudden appearance and disappearance of the hallucinatory images which had seemed quite real to her.

No special treatment for bromide intoxication was given. Her depression did not improve and she was again discharged against advice on March 9, 1935.

The serum bromide on readmission January 11, 1935 was 200 mgm per cent (25 mM/L). On January 27 the serum bromide was 75 mgm per cent (9.3 mM/L) and on February 13 bromide was not detectable.

Comment Although the patient was already eating poorly, bromide was given in an attempt to manage an agitated depression in the home. An intoxication quickly developed. The patient was not seen by a psychiatrist during the hallucinated period, but the history suggests a pure hallucinosis, not a delirium. Only three cases of bromide hallucinosis have previously been reported¹.

CASE 3 C. B. aged thirty-seven a policeman was admitted on January 19, 1935. He had been addicted to alcohol for over fifteen years. Early in December 1934 after a prolonged alcoholic debauch during which little food was taken on upper respiratory infection occurred followed by a delirium with disorientation and visual hallucinations. He was restless, ate poorly and attempts to quiet him with opiates and chloral hydrate were unsuccessful. He had been given six grams of bromide daily for eight days before admission to the Psychiatric Clinic.

On admission the vital signs were normal. He was markedly dehydrated and there was a diffuse acneiform rash on the face and shoulders. Speech was slow and thick. A high caloric diet rich in vitamins was given with 5000 cc. of fluid and ten grams of sodium chloride daily. In four weeks the delirium subsided and there was marked improvement in his physical condition. He was discharged on February 23, 1935.

On admission January 19, 1935 28 per cent of the total serum chloride was displaced by bromide. The serum bromide was 235 mgm per cent (27.2 mM/L). On January 27 the serum bromide was 125 mgm per cent (15.0 mM/L) and on February 13 serum bromide was not detectable.

Comment Although the patient was already suffering from a toxic delirium and had been eating poorly, bromide was given in an attempt to control psychotic symptoms. Bromide intoxication quickly developed.

CASE 4 C. M., aged forty-nine a widowed hair dresser was admitted on March 7, 1935. In August 1934 she had complained of fatigue, insomnia, palpitation and nervousness. She ate very poorly. She refused to consult a physician until February 1935 and at that time refused hospitalization. Four grams of bromide were administered daily since February 14, 1935. After two weeks her speech became thick, and her actions sluggish and she became restless and hallucinated. She was then hospitalized for nine days with continued bromide medication. Her condition did not improve and she was transferred to the Psychiatric Clinic.

On admission the vital signs were normal. There was no skin eruption. A fine tremor of the outstretched hands and a suggestive bilateral lid lag were observed. A severe symptomatic psychosis was present with disorientation, fluctuation of the level of awareness, auditory hallucinations and periodic attacks of low grade panic.

Elimination of the bromide was facilitated by hydration, and the administration of ten grams of sodium chloride daily. In two weeks the delirium subsided. Definite signs of thyrotoxicosis were then seen. The sleeping pulse rate varied between 100 to 120 per minute and the basal metabolic rate varied from +25 to +35 per cent. After two weeks administration of Lugol's solution a subtotal thyroidectomy was done on April 9, 1935. The postoperative course was uneventful. The basal metabolic rate varied from -2 to +6 per cent and the sleeping pulse rate was 70 to 80 per minute. Her symptoms improved slowly and she was discharged on May 6, 1935.

On admission 30.2 per cent of the serum chloride was displaced by bromide. The serum bromide was 225 mgm per cent (23.1 mM/L). On March 10, 1935 serum bromide was 60 mgm per cent (7.5 mM/L) and on March 25 serum bromide was not detectable.

Comment Symptoms of thyrotoxicosis were not recognized. Although the patient was already eating poorly, bromide was given in an attempt to control supposedly functional symptoms. Intoxication quickly developed. The correct diagnosis of the underlying condition was possible only after the bromide had been eliminated.

CASE 5 S. K. aged forty-seven a housewife, was admitted on March 25, 1935. About one year previously she had begun to complain of depression, retardation and irritability. She resorted to drinking large quantities of alcoholic beverages, took little food and after a few months developed a severe polyneuritis. She became bedridden and several physicians considered her condition grave. The administration of bromide was begun on March 10, 1935 and she received approximately 120 grams of sodium bromide in two weeks.

On admission the patient was stuporous. The vital signs were normal. The tendon reflexes of the arms were hyperactive. Both legs showed diffuse muscular atrophy, absent tendon reflexes and suggestive foot drop. There was a slight acneiform rash on the face and back.

Eight grams of sodium chloride were given daily with a diet high in caloric and vitamin content. Fluids were forced. After a few days the stupor cleared and disorientation, fluctuation of awareness and hallucinations were observed. The delirium and the neuritis improved rapidly under treatment. After the delirium subsided an irritable hypomanic condition was left, which disappeared within a week.

On admission 48 per cent of the serum chloride was displaced by bromide. The serum bromide was 350 mgm per cent (43.7 mM/L). On April 8, 1935 the serum bromide was 100 mgm per cent (12.5 mM/L), and on April 18, the serum bromide was 50 mgm per cent (6.25 mM/L).

Comment Although the patient was already in a critically malnourished condition, and had an alcoholic avitaminotic neuritis, bromide was used in an attempt to quiet her. Severe intoxication quickly developed.

CASE 6 S W, aged forty one, a housewife, was admitted on April 6, 1935. Four years previously a diagnosis of parenchymatous neurosyphilis had been made and confirmed by cerebrospinal fluid serology, pleocytosis, and increased protein content. She had received no specific treatment. For the past six years she had complained of irregular periodic girdle pains which had been interpreted as "heart attacks". The pain always began suddenly, bore no relation to exertion, and was not associated with dyspnea. Opiates had relieved it. A number of weeks before admission, bromide had been prescribed in an attempt to relieve one of these attacks. The drug had been continued indefinitely and had been purchased in pint size bottles. She became stuporous and ate very little food. No convulsions had occurred.

On admission the vital signs were normal. The pupils were fixed to light. There was no skin eruption. The blood Kahn was negative. The cerebrospinal fluid was under normal pressure and contained eight lymphocytes per c mm. The Pandy reaction was strongly positive. The cerebrospinal fluid Wassermann was +4, and the colloidal gold curve was 4555555554.

A typical delirium was present with disorientation, fluctuation of awareness, and restlessness. The patient's general condition was poor, and parenteral saline was given to hasten the elimination of bromide. Because of extreme noisiness, morphine and hyoscine had to be given on several occasions. Her condition did not improve. She became stuporous, developed bronchopneumonia and died on April 24, 1935.

On admission the serum bromide was 350 mgm per cent (43.7 mM/L). This was one week after bromide had been discontinued.

On April 2, 1935 the serum bromide was 150 mgm per cent (18.7 mM/L).

Comment Excessive quantities of bromide were given in an attempt to relieve attacks of tabetic pain. No attempt was made to control the chloride-bromide balance. A severe intoxication developed and the patient died of an intercurrent bronchopneumonia before the intoxication could be controlled.

Postmortem examination of the brain The gross appearance of the brain was entirely normal excepting the cerebral meninges, which appeared slightly thickened and cloudy. The Turnbull test for iron in the cerebral cortex was negative. Microscopic examination showed the cerebrospinal meninges infiltrated with small numbers of lymphocytes and plasma cells. This exudate was most marked in the meninges at the base of the brain and around the brain stem. There were none of the stigmata of general paresis. Sudan III and Weigert preparations

of the spinal cord failed to reveal any evidence of tabes.

Throughout both occipital lobes were found numerous small patches of necrobiosis. These had a focal distribution and were limited to the cortical grey matter. None of the large pial or parenchymal vessels showed organic change. The cortical capillaries revealed marked endothelial swelling. Both temporal lobes showed a similar picture to a lesser extent. These changes resembled in all respects those found in functional vascular disease, having been described following epileptiform attacks.

CASE 7 A M, aged twenty four, a single man was admitted on April 21, 1935. Seven weeks previously he had fallen, striking his head and suffering concussion with hemorrhage from the mouth and right ear. He had been hospitalized, and had remained unconscious for five days. Roentgenograms of the skull were negative for fracture at that time. During the next few days he became restless and unmanageable. He was placed on a dehydration diet and six grams of bromide were administered daily in an effort to combat the post-traumatic excitement. He became stuporous, and then after three weeks became overactive, talkative, disoriented and hallucinated. On April 12, 1935 he was discharged from the hospital unimproved, with instructions to his family to continue the administration of three grams of bromide daily. At home he continued confused and restless, and admission to the Psychiatric Clinic was advised.

On admission the vital signs were normal. Severe dehydration was present. There was a diffuse acne-form rash on the face and back. Neurologic examination was negative except for a right lower facial weakness. The cerebrospinal fluid pressure, color, protein and cell content were normal. The cerebrospinal fluid Wassermann was negative. A typical symptomatic psychosis was present with fluctuation of awareness, disorientation, confabulation, visual hallucinations, and restlessness. Speech was thick and slurred.

He was given ten grams of sodium chloride daily and a diet high in caloric and vitamin content. Fluids were forced. Wet sheet packs were used for sedation. In four weeks the delirium subsided, and his general physical condition showed great improvement, although the right facial weakness persisted. He was discharged on May 19, 1935 with instructions to return to the Neurologic Outpatient Clinic.

On admission 47 per cent of the total serum chloride was displaced by bromide. The serum bromide was 350 mgm per cent (43.7 mM/L). On May 6, 1935 the serum bromide was 200 mgm per cent (25 mM/L), and on May 13, 1935, the serum bromide was 60 mgm per cent (6.25 mM/L).

Comment Bromide was given in an attempt to control a posttraumatic delirium, and the patient was simultaneously given a dehydrating diet. Severe intoxication quickly developed. Hydrotherapy produced an excellent sedative effect.

CASE 8 S H, aged thirty one, a single man, was admitted on May 8, 1935. He had had petit mal attacks since fourteen and grand mal attacks since twenty-eight years of age. Phenobarbital and a low protein diet had been administered in an attempt to control the convulsive state. During March and April, 1935, the attacks had become more fre-

quent, and five grams of bromide had been administered daily. After about ten days of bromide treatment he had become sluggish in speech and action. On April 28 1935 a consultant diagnosed his condition as an organic psychosis and advised withdrawal of the drug. At that time the serum bromide was 300 mgm per cent (375 mM/L). Fluids were forced and sodium chloride was administered but the patient remained sluggish. Admission to the Psychiatric Clinic was suggested.

On admission the vital signs were normal. There was a diffuse chronic acne vulgaris on the face, shoulders and back that had recently become more severe. No other physical abnormalities were noted. No evidence of delirium was observed but there was definite mental sluggishness.

After ten days of hydration and increased sodium chloride intake the sluggishness disappeared. The patient then had a major convulsive attack and was given phenobarbital daily. He was discharged on May 18 1935 with instructions to continue the use of phenobarbital.

On admission 30 per cent of the serum chloride was displaced by bromide. The serum bromide was 225 mgm per cent (281 mM/L). On May 11 1935 the serum bromide was 75 mgm per cent (93 mM/L).

Comment. Large amounts of bromide were given in an attempt to prevent epileptic convulsions without any attempt to control the chloride-bromide balance. Moderate intoxication quickly developed, which fortunately was recognized before it became severe.

CASE 2. H. H., aged sixty-three, a widowed housewife was admitted on May 27 1935. For five years she had complained of attacks of precordial pain radiating to the left arm sometimes associated with dyspnea and pulmonary edema. During the past two years these attacks had become more frequent, and the patient had become more garrulous, circumstantial and irritable. In February 1935 she was hospitalized and a diagnosis of general coronary and cerebral arteriosclerosis was made. A diet low in fluid and sodium chloride was ordered. In May 1935 after an anginal attack bromide was prescribed and she received seventy-five grams of the drug in two weeks. On May 16 1935 she complained of poor vision and in a few days became confused, disoriented and hallucinated.

On admission the vital signs were normal. The tendon reflexes were hyperactive. There was a slight acneiform rash on the back. Disorientation, fluctuation of awareness, and visual and auditory hallucinations were present.

She was digitalized, fluids were forced and she was given eight grams of sodium chloride daily. The delirium subsided after three weeks, her general condition improved and she was discharged on June 24 1935.

On admission the serum bromide was 300 mgm per cent (375 mM/L). On May 31 1935 the serum bromide was 175 mgm per cent (219 mM/L). On June 11 1935 the serum bromide was 50 mgm per cent (625 mM/L).

Comment. Bromide was given, in an attempt to control anginal pain to an arteriosclerotic patient who was already on a restricted fluid and chloride intake. Severe intoxication quickly developed.

DISCUSSION

Cases of bromide intoxication with symptomatic psychosis have been seen surprisingly frequently in southern Connecticut. Two and seven tenths per cent of the patients admitted to the Psychiatric Clinic at New Haven Hospital during the past year have shown signs of definite intoxication with bromide. The nine cases reported here illustrate various aspects of the clinical problem.

The administration of bromide is clearly indicated only in the treatment of certain patients with organic convulsive diseases. Notkin¹² has shown that fairly large amounts of bromide may safely be administered indefinitely to epileptics if the chloride-bromide balance is carefully controlled, and if occasional determinations of the blood bromide content are made. Bromide in doses of one to two grams a day is sometimes useful in the management of mild nervous and mental symptoms although in most cases a rapidly acting barbiturate such as sodium amylal is more effective. In the presence of renal damage, however, barbiturates are more dangerous than bromide. It must be kept clearly in mind that bromide must not be administered over any prolonged period unless an adequate intake of fluids and chloride is maintained, and the physician should be constantly alert for symptoms of bromide intoxication.

Bromide should not be employed in states of severe excitement and agitation because it is not effective unless dangerously large doses are given. Paraldehyde is not only more effective but is much safer in such states. Bromide should never be used in cases of delirium due to either toxic or infectious causes. It should be used with caution in cases of arteriosclerosis, since delirium is readily produced if cerebral arteriosclerosis is present. Nephritis is a definite contraindication to the use of the drug.

Bromide should not be used in cases of dehydration or severe malnutrition, in which the body fluids and chlorides are low.

In eight of the nine cases reported, deficient diet and dehydration seemed to play a definite rôle in the development of bromide intoxication. This fact has not been sufficiently emphasized in the literature.

An inadequate intake of fluids and chloride would seem as important a factor in producing bromide intoxication as the actual amount of bromide taken. The experience of Notkin¹² with epileptics illustrates this point clearly.

The skin eruption is not a reliable criterion of bromide intoxication. The question of bromide exanthems will be discussed in greater detail in a subsequent paper. A skin eruption was present in six of the nine cases in our series but in no case was it considered severe enough to be in itself an indication for treatment.

The management of psychiatric illnesses in the community is no simple problem. Sedatives are often necessary, and the patient or his family may refuse to consider hospitalization. The attending physician has to make the best of the situation.

More general appreciation of the importance of the recent studies of bromide intoxication, however, will facilitate the successful management of such cases.

SUMMARY

1 Nine cases of bromide intoxication with symptomatic psychosis are reported.

2 The pharmacology of bromide is summarized, and the symptomatology, diagnosis, and treatment of bromide intoxication are briefly reviewed.

3 The frequency of bromide intoxication in southern New England is noted.

4 Reasons for the occurrence of bromide

intoxication are advanced, and suggestions for its prevention are offered.

AN ANALYSIS OF THREE HUNDRED CASES OF ASTHMA IN CHILDREN*

BY EDWARD SCOTT O'KEEFE, M D †

THE bulk of the work upon asthma deals with groups composed either solely or in a large part of adults. The problem of asthma among children is sufficiently different to warrant its separate consideration. This series is

CHART 1 The Age at Onset of 300 Cases of Asthma in Children

composed of 300 children, under fourteen years of age, who have been seen by me at the Massachusetts General Hospital during the last three years. The average age of the patients at the time of examination was seven years and nine months.

*From the Anaphylaxis Clinic and the Children's Medical Service of the Massachusetts General Hospital.

†O'Keefe Edward S — A B M D Associate Pediatrician, Massachusetts General Hospital. For record and address of author see "This Week's Issue" page 83.

Between twenty and fifty protein tests were done upon each child, the common food, animal and pollen allergens being used. The scratch test was most commonly employed, although in the last year, many of the pollen and animal emanation tests were done by the intradermal method as well. The combined methods gave a much higher percentage of positive tests in pollen disease than we had secured by using the scratch test alone¹.

The age of the onset of asthma was first considered and is shown in graphic form in the accompanying chart. The exact time of onset is often difficult to determine with any degree of accuracy since the early attacks are frequently mistaken for respiratory infections. However, one case in the series began as early as the second month, two in the third month, one in the fourth, and one in the fifth month. Cases having their onset after the sixth month were not infrequent. About 10 per cent had their onset in the first year, and 12 per cent in the second year. Sixty-six per cent began during the first six years. After the sixth year a sharp drop occurred in the incidence of new cases. The average age of onset for the entire group was 4.6 years.

Results not markedly at variance with these figures were reported by Chobot and by Peshkin. Chobot² in a series of 100 children found that 10 per cent of the cases had their onset in the first year and 19 per cent in the second year. Peshkin³, in a group of 100 children, states that he found the commonest age of onset to be the second year.

There is a general impression that an allergic

family tendency influences the time of onset of asthma. A series of adults reported by Spain and Cooke⁴ showed the average age of onset for patients with a positive family history to be twenty five years. Those having a negative family history had an average age of onset of thirty five years. The allergic families developed asthma much earlier than did the non allergic families. These authors included under the heading of a positive family history those cases having a positive collateral family history as well as those having a direct family history of asthma or hay fever. Using these limitations they found that 58.4 per cent of their series of 462 cases had a positive antecedent family history. Moreover they ascertained, in a group of 115 normal individuals, that only 7 per cent had such a positive history. In 52.9 per cent of thirty four cases having a bilateral family history the onset of symptoms occurred in the first five years of life and in 26.4 per cent the onset occurred in the second five years of life.

In our children's series, no such difference was found between these two groups. Children with a positive family history showed an average age of onset of 4.3 years while the children having a negative family history showed an average age of 4.4 years. The group showing a positive family history either of direct or collateral inheritance, was further analyzed. Twelve cases had a bilateral inheritance. In this group the average age of onset was 4.7 years. Fifty eight cases having a unilateral inheritance showed an average age of onset of 4.1 years. As noted above the group of 172 cases having a negative family history showed an average age of onset of 4.3 years. So it is seen that there is shown no significant difference in the age of onset of asthma in children whether the family history is negative or positive.

The influence of an allergic family tendency upon the occurrence of complicating allergic conditions was noted also its influence upon the incidence of sensitization to more than one group of allergens. Of the total 300 cases 38 per cent showed a positive allergic family history, and of these, 28 per cent showed eczema, hay fever, or other allergic conditions complicating the asthma. Of those having a negative family history, 23 per cent showed allergic conditions complicating the asthma. Individuals from the allergic families were apparently somewhat more prone to the development of complicating allergic conditions.

The question of multiple sensitization in relation to the family history is pertinent. Of the children with a positive family history, 30 per cent showed multiple sensitization. The nonallergic family group showed that 34 per cent of their number were sensitive to more than one of the four groups of allergens which

would indicate that the allergic family tendency is not a factor of importance in this connection.

Children with allergic heredity are more apt to develop allergic diseases than are children with a normal heredity, according to Bilyeat.⁵ Such children do not, however show any great difference from the nonallergic group in the age of onset of their asthma, nor in the frequency with which they manifest multiple sensitization.

An analysis of the cases from allergic families showed that one or both parents were allergic in 40 per cent of the group, in 37 per cent the grandparents had been allergic, in 16 per cent the brothers or sisters were allergic. Of 178 cases in this group, the relatives showed asthma in 53 per cent of the cases, hay fever in 26 per cent, eczema in 13 per cent, urticaria in 1½ per cent, migraine in 1½ per cent, and vasomotor rhinitis in 1 per cent. There seems to be a marked tendency for families to show the same allergic condition in succeeding generations viz asthmatic parents transmit a tendency toward asthma rather than toward one of the other allergic conditions.

The question arises as to whether the early onset of asthma has any significance in forecasting the occurrence of complicating allergic diseases. Will the patient who shows asthma in the early years be more apt to develop hay fever, for instance, than the child whose asthma appears later in childhood? A tabulation showed that there were 214 cases of asthma which were uncomplicated by other allergic conditions, and that there were 86 which were so complicated. The first group showed an average age of onset of 4.1 years, the second group showed an average age of onset of 3.2 years. This would seem to indicate that the earlier the asthma manifests itself the more likely the patient is to develop complicating allergic conditions.

CHART 2 The Relative Importance of the Common Allergens at the Various Ages

The importance of the various groups of allergens at different ages is an interesting study. This is graphically shown in Chart 2. This chart shows foods and animal emanations to be of about equal importance during the second

veal, pollens to be of but little importance, comparatively. From the second year on, for several years, the animal emanations become more important and the foods less important. Pollens remain comparatively unimportant until the ninth year, when they are found to show the highest percentage of positive tests. All the allergens show a peak during the eighth and ninth years, and again during the thirteenth and fourteenth years.

It is obviously desirable to limit as much as possible the number of protein tests when dealing with children. With this object in view, an analysis of the tests was made. Of the many food allergens for which tests were made, a small group appeared to be of primary importance. There were 155 positive tests for foods. Of these, 21 per cent were for egg, 18 per cent for wheat, 9 per cent for milk, and 6 per cent for potato. The four foods just mentioned account for 54 per cent of the 155 positive tests for foods. The remaining 46 per cent of the group was divided among the common fruits, vegetables, meats, nuts and cereals, other than wheat. Not one of the foods in this latter group was found positive in over 1 per cent of the total positive tests. Turning to the group of animal emanations we find 257 positive tests, of these 31 per cent were due to cat, 24 per cent to dog, 18 per cent to horse, 15 per cent to chicken feathers, 6 per cent to goose feathers. Cattle hair, rabbit hair, parrot feathers, wool and duck feathers occurred occasionally. The pollens gave a total of 256 positive tests. Of these tests 30 per cent were due to ragweed, 18 per cent to timothy, 17 per cent to orchard grass, 16 per cent to red top, 7 per cent to cocklebur, 6 per cent to plantain. Other pollens were included in the tests but none accounted for more than 1 per cent of the series. House dust was frequently found positive. Its clinical significance is difficult to determine. Orris powder occurred occasionally.

Of the entire 300 cases, 67 per cent were found positive to one or more allergens, 47 per cent to animal emanations, 29 per cent to pollens, 25 per cent to foods, and 5 per cent to miscellaneous factors. Comparing these figures with those reported by Rackemann⁶, for a group composed mainly of adult patients, we find that animal emanations and foods play a much less important rôle than is the case among the children.

The accompanying table shows the comparative importance of the four great groups of allergens in children and in adults. Many of the cases, of course, showed sensitivity to one or more of these groups.

A consideration of table 1 shows the foods and the animal emanations much less frequently positive among adults than is the case among the children. It seems fair to say that

this is in most instances to be attributed to natural desensitization. It indicates a better prognosis among children for the recovery from asthma due to either of these two factors than is the case in the pollen asthma, which shows as high a percentage of positive tests in the

TABLE 1

	Rackemann Adult Group 924 Cases	O'Keefe Children's Group 300 Cases
Positive tests	46%	67%
Animal emanations	17%	47%
Pollens	33%	29%
Foods	7%	25%
Miscellaneous	5%	5%
Negative	54%	33%

adult group as occurs in the children's groups.

The group reported by Rackemann is composed mainly of adults. It contains 425 cases classified as extrinsic asthma and 499 cases classified as intrinsic asthma. In the extrinsic group positive tests were found in 82 per cent of the cases, in the intrinsic group the percentage was 17. The average of these two groups as shown in our table is 46 per cent. The children's group, in table 1, is composed of extrinsic and intrinsic asthma, and shows that 67 per cent of the cases exhibited positive tests.

CONCLUSIONS

About 10 per cent of the cases of asthma in children have their onset in the first year of life, 66 per cent have their onset during the first six years.

A positive family history of allergic disease does not influence the age of onset of asthma in children, or the frequency of multiple sensitization. Individuals from allergic families are, however, somewhat more prone to the development of complicating allergic conditions than are children from nonallergic families. As originally pointed out by Adkinson⁷, there is a definite tendency to show the same allergic condition in succeeding generations.

In the first year of life the foods show the highest percentage of positive skin tests. In the second year, however, and after that the animal emanations become of chief importance, until the ninth year when they are surpassed by the pollen antigens. In the thirteenth and fourteenth years the percentage of positive tests for all the antigens shows a very marked and sudden increase. This is especially true for the animal emanations. The onset of puberty may, in some way, be responsible for this sudden change.

The most important allergens concerned in the asthma of children are as follows:

Foods	Animal Emanations	Pollens	Miscella- neous
egg	cat	ragweed	orris powder
wheat	dog	timothy	house dust
milk	horse	orchard grass	
potato	chicken feather	red top	
	goose feather	cocklebur	
		plantain	

From this group of seventeen allergens the examiner will usually obtain information as to which group or groups should be more intensively investigated

MEDICAL PROGRESS

PROGRESS IN DERMATOLOGY, 1935

BY HARVEY F. TOWLE, M.D.* AND JACOB L. GRUND, M.D.*

ALLERGY

SOME years ago a physician in a suburb of Boston was heard to declare that syphilis had now become a routine affair. If the Wassermann is positive the diagnosis is syphilis. If the diagnosis is syphilis you give arsenphenamin. And that is all there is to syphilis now a days. It would almost seem that a similar situation is developing in regard to allergy and the food tests, if one judges by the literature. Many physicians seem to believe that if one has to deal with a skin eruption the food skin tests will absolutely reveal both diagnosis and treatment. You test the skin with various bits of food. If you get a reaction the eruption is allergic. If the eruption is allergic you take away the foods which caused a reaction and the patient gets well. That's all there is to allergic eruptions.

The editorial writer in the *New England Journal of Medicine*¹ does not think the matter quite so simple as that. He has thus to say about the allergic skin tests: "It would seem that promiscuous skin testing should become a thing of the past. Proper selection of patient and test should be made in order to gain the proper scientific data and not subject the patient to unnecessary tests and expense. At the same time thought should be given to the variations in tests from time to time. Their evaluation demands experience and common sense."

Colmes² is even more specific and emphatic. He opens his article by saying "That the diagnostic import of the protein skin test is not infallible and that frequent irregularities exist in the relationship between the skin reacting allergen and the patient's symptoms, has been recognized since the early studies on human

hypersensitiveness." In confirmation of that statement Colmes quotes a number of authors, Blackfan who has seen an "egg" eczema with a negative egg test, Walker who found that positive skin tests cannot always be incriminated as causative of the patient's symptoms, Schloss, who had the same experience as Walker, also Kern, Maytum, Rackemann, Feinberg, Stevens, Rowe, and Hill. Surely men of such repute would lend credence to any statement. After giving the tables of the results of his own studies Colmes concludes: "These results indicate that, in the study of allergic diseases, the positive skin reaction cannot be accepted as the sole basis for determining the offending factor."

Rackemann³ at a recent symposium on allergy pointed out the increasing importance of the history and the decreasing significance of the skin test. A "good allergen" gives a typical wheal in a few cases and a negative reaction in most cases of routine testing.

Schmidt⁴ brings out another point in regard to evaluating skin tests. He states that the various regions of the body do not react alike. The back reacts more strongly than the upper arm, the flexor surfaces than the extensor, the upper arm than the forearm. Hence in comparing results, one must make sure that all tests were made on the same region of the body. For instance, one should not compare a test made on the back with one made on the forearm. As to the back itself Schmidt reports that wheals induced four fingerbreadths below the spine of the scapula were only half as large as those produced in the region of the spine of the scapula itself.

Urbach⁵ has worked out a theory to explain why the allergic tests respond in one region and do not in another. The foundation of every clinical manifestation of an allergic disorder he says, is an antigen antibody reaction. In the main, the important factor in the manifestation

*Towle, Harvey F.—A.B., M.D., Consultant in Dermatology Massachusetts General Hospital, G and, Jacob L.—M.D., Assistant Dermatologist Department of Dermatology and Syphilology Massachusetts Memorial Hospitals. For record and addresses of authors see "This Week's Issue" page 23

are those of a physical hypersensitiveness "there is no reason why it should not be regarded as allergic, since allergy is the abnormal response to a normal stimulus" Dubbs' case is that of a woman sixty-two whose skin when exposed to cold air or cold objects, developed itching and redness of the exposed parts. Perfectly typical wheals could be produced on any part of the body, at will, by the application of ice or other cold objects. If the patient walked briskly in the cold air, the skin symptoms would be accompanied by dyspnea and palpitation. The attacks never lasted more than five or ten minutes. The patient never had had any other form of allergy and her family history was entirely negative. The reporter notes that subcutaneous injection of epinephrin hydrochloride promptly relieved all symptoms and that fifteen grams of calcium lactate given three times a day caused a marked reduction in the intensity and frequency of the attacks. With the cessation of medication there was a return to the former status in quo.

Allergists have long considered asthma, eczema and urticaria as true examples of allergy and, from the study of them, have advanced various theories to explain the allergic phenomena. Now Vallery-Radot and Blamoutier¹⁴ add to the long list of investigations. They use aqueous extracts of the spleen from which all possible albumins had been removed. They report that the injections were painless and, as a rule, provoked no untoward reactions. They further report that their best results were obtained in acute vesicular eczema. The results are said to have been rapid and sometimes lasting and permanent. In some cases the pruritus was modified although the eruption was unaffected. Dry eczema did not respond to the therapy. In urticaria of digestive origin they obtained results but cases of other origin were refractory. Quincke's edema was not influenced by the treatment. They report that frequently splenotherapy acted very favorably on the general well-being. They obtained cures in twenty-one cases of eczema out of forty-nine treated and improvement in twelve others. In thirty-five cases of urticaria treated they got cures in only eight and improvement in seven. Asthma was even less influenced than urticaria for they report that only four of seventeen cases were materially modified.

Most writers have busied themselves in explaining how a given disease is related to allergy. Browning¹⁵ attacks the problem from an exactly opposite point of view in his paper on ringworm. Browning argues the thesis that ringworm of the extremities is a result of complication of hypersensitiveness rather than that hypersensitiveness is a complication of ringworm. He argues that the trichophyton finds lodgment because the "allergic balance", as he calls it, is disturbed. He asserts that when

this allergic balance is destroyed measures directed directly against the trichophyton are unnecessary. Cure follows without them. He finds support for his theory of an "allergic unbalance" in the existence of other allergic manifestations or signs, especially in the skin. By treating the allergic state rather than the trichophyton he is able to report excellent results in thirty cases. He explains the good results obtained by ordinary treatment by the supposition that such methods restore the "allergic balance" to the affected parts. As further proof that his method of attack is logical and justifiable he points to the fact that his results were obtained in the face of the fact that the microscopic search for the fungus was positive in every case reported. Improvement, he says, usually begins within two weeks if the case has been correctly diagnosed and if instructions have been followed.

INDUSTRIAL SENSITIZATION

The compensation laws of the various states and countries have given a new importance to the various forms of cutaneous disease which arise from industrial and commercial products. Particularly have they given rise to an intensive search for the exact offending substance in these processes and compounds. For example, whereas not so very long ago we were content with the diagnosis of Baker's eczema now we must know just what substance it is which causes the dermatitis. It is no longer called eczema. Zitzke¹⁶ reports that in 149 cases of Baker's dermatitis 41 per cent showed sensitivity to pure flour alone while 67.2 per cent showed sensitivity to chemically treated flour, as determined by the patch test. The chemicals used in treating flour are ammonium persulphate, calcium phosphate, and potassium bromate. Testing these three substances separately, it was found that the subjects reacted positively to the ammonium persulphate but were consistently negative to the calcium phosphate and potassium bromate. Hence Zitzke concludes that it is the ammonium persulphate which causes the dermatitis.

In view of the widespread use of hexylresorcinol by the laity there is interest in Dr. Walter's report of a case of sensitization to that remedy.¹⁷ The patient was a woman who came of an allergic family, was allergic herself to strawberries and tomatoes, and who had two daughters who were subject to attacks of asthma. The patient had used hexylresorcinol dressings on a leg ulcer for five months. Later she used hexylresorcinol to clean out a wound on the hand. The result was a tremendous swelling of the hand with the formation of vesicles and large bullae.

Balsam of Peru has been used freely in our dermatological and surgical clinics without a thought of harm resulting. Yet Engelhardt¹⁸

reports that 2 per cent of people who have never had any skin disease or used ointments are hypersensitive to balsam of Peru and that 10 per cent of those who have had skin disease and who have used ointments are also sensitive. All of the constituents of the balsam are involved for they all give positive results to test reactions. Hence Engellhardt concludes it is not advisable to continue the practice of using the balsam over large wound surfaces or in eczema. If it is desired to use it he advises that patch tests be made first.

Tobias¹⁹ writes that 'perfume dermatitis' is not common in this country when one considers that thousands of bottles of various types and grades of perfume are sold annually. Unfortunately the literature contains very few reports of true perfume dermatitis. These cases are fairly common in France he says. Tobias describes three types of dermatitis which may be caused by perfume. The first type is dermatitis venenata which can be produced by the irritants in the perfume coming in contact with the skin at the first application without the intervention of hypersensitivity. He compares this type to the dermatitis produced by benzene or turpentine. The second type is that produced by specific ingredients of the perfume such as aldehydes,orris root, or dyes which after long use, produce a specific hypersensitization (contact or eczematous dermatitis). A third type of perfume dermatitis was first described by Freund in 1916. This one is known as *Berloque Dermatitis*. This form occurs as a streaked erythematous eruption which is followed by pigmentation. The cause is sunlight acting upon the skin through a film of the oil of bergamot, a common ingredient of toilet waters and cologne.

Tobias gives seven rules for making the diagnosis

1. The location of the eruption. It occurs naturally on the regions to which the perfume has been applied.
2. Its sudden appearance.
3. Intense itching and burning. The intensity of these symptoms is usually out of all proportion to the extent of the eruption.
4. The time element. According to Sulzberger and Kerr there are two periods in the development of the hypersensitivity—(a) a period of incubation or formation of hypersensitivity which varies from months to years, and (b) the period of reaction which is usually constant varying from twenty-four to seventy-two hours.
5. The type of eruption. The berloque type is usually linear and followed by pigmentation after exposure to sunlight. The contact type is erythematous or vesicular.
6. The diagnosis by means of the patch test, as the sensitization is epidermal.
7. The history, elicited by close and repeated questioning.

Baer²⁰ in commenting upon Tobias' article

relates that in connection with his study of lip stick dermatitis he had found methyl heptane carbonate to be the specific offending substance. He states that this substance is derived from ricinoleic acid and is widely used by perfumers for its violet odor. Baer found that over 50 per cent of both men and women were sensitive to it. The patch test was the proof.

CANCER

For years the debate has been going on as to when a carcinoma is not a carcinoma. Is cancer always a cancer and if not, when does a one time benign growth become cancerous? Sutton²¹ debates these questions in a very interesting fashion. He is inclined to believe that, at least in many instances, cancer is cancer from the start. He begins his article by quoting a case to substantiate his thesis that 'cancerous lesions come into existence on sites previously normal a common experience'. He agrees with Brodn that "the entity called carcinoma regardless of etiology, is a primary disease of epithelial cells and all other phases and sequelae, though of great importance, are in reality of secondary nature".

Sutton has done an enormous amount of research on the subject but acknowledges that all such work is of necessity incomplete. In order to make such work complete one should have started with the normal skin and have followed its various changes through to actual, demonstrable cancer formation. Naturally, one can not do this. Instead one must be content to study specimens taken from various persons and from various growths. As one cannot follow through the evolution of the cell in one patient, one must be satisfied with a series of static pictures taken so nearly as one can manage, from growths of various ages. In spite of this insurmountable obstacle, Sutton has studied enough cases to have reached certain very definite conclusions.

'1 (a) Many cancers begin as de novo lesions. (b) The earliest visible lesion in these cases is a circumscribed, scaly, epithelial new growth.

'2 (a) The structure of many minute, scaly, epithelial new growths is such that it is reasonable to presume that, if not interrupted they would become obvious carcinomas. (b) It is reasonable to believe that such lesions are in fact early carcinomas. (c) If a lesion has a structure not compatible with a likelihood of its being early carcinoma, it might be called precancerous. But it would be impossible to predict that such a lesion might, if not interrupted, develop a structure such that it would be properly called carcinoma.

'3 (a) It is impossible to determine at what point in its natural history a cancerous lesion is not cancerous. (b) It is reasonable to

believe that cancer is cancer from the start

"4 The concept of precancerosis is indecisive and undefinable. It groups unrelated conditions which may or may not be early cancer. Its acceptance entails an insoluble problem of a dividing line between cancer and not-cancer, as well as a statistical assay of lesions that are strictly individual.

"5 (a) A lesion may be cancerous independently of its size and rate of growth. (b) Cancer is primarily an epithelial disease. (c) Cancer consists of mutated somatic cells. (d) The earliest visible manifestations are circumscribed, dyskeratotic lesions which microscopically are composed of polymorphous epithelial cells that proliferate, keratinize and undergo mitosis in an abnormal manner. (e) Malignancy depends on a balance between proliferative capacity of its cells and the control or resistance of its host. (f) One tumor may contain several kinds of cells as a result of mutation following on mutation."

Riecke²² describes a rare form of cutaneous carcinoma in a woman of sixty-two. The first manifestation occurred a year before when a nodule appeared on her thigh. The nodule enlarged and suppurated. An erysipelatous process developed, after which fresh nodules appeared accompanied by a severe swelling in the groin which perforated. Fresh nodules continued to appear which always followed the same course, softening, disintegration and an exudate of serous fluid. Various diseases were considered in the differential diagnosis such as syphilis, tuberculosis and blastomycosis. After observation and study these diagnoses were rejected and Riecke became convinced that the disease was an abnormal form of cutaneous carcinoma. This conclusion was confirmed by the microscopic examination which disclosed a basocellular carcinoma. Riecke has seen one similar case.

Franseen and Taylor²³ report nine cases of carcinoma unquestionably due to arsenic, five probable cases and one case in which only keratoses developed. They state that arsenic may be deposited in the skin and there manifest its carcinogenic powers as late as forty years after the exposure. In their opinion the carcinogenic property of arsenic is not properly appreciated so that cancer is sometimes produced by accident. Fowler's solution, the inorganic trivalent form of arsenic, seems to be the chief offender. Chronic arsenical lesions seem to be rare after the administration of the organic compounds. While the squamous cell carcinoma is the ordinary type, more than one third of all arsenical carcinomas are said to be of the basal cell type. Although the malignancy of the squamous carcinoma is low, metastases are not infrequent. Hence the writers advise that the regional lymph nodes should be re-

moved in all cases of growths of considerable size.

Laboratory workers have now for a long time used mice in the study of cancer and by such studies have added much to our knowledge of human cancer. Mottram's article²⁴ on the relationship and the rapidity of the growth of tar warts in mice has, therefore, much of interest to us. Analyzing the time of appearance in its relationship to malignancy, Mottram found that malignant warts appear more slowly after the tarring than do the benign. So too, he found that warts which appeared late grew faster than those which appeared early. Sessile warts are largely malign whereas pedunculated and horny warts are usually benign. Sometimes a sudden increase in growth was noted and in all such cases the wart was found to be malignant. As a rule, he states, benign warts grow slowly and malignant warts grow rapidly. Moreover he found a close relationship between ulceration and malignancy. Mottram's statement that "autografts show that there is a continuous development and change in warts from benign to semimalignant, from semimalignant to malignant" bears out Sutton's²¹ contention that cancer may arise *de novo* and that cancer is cancer from the start.

Dunn and Smith²⁵ report the unusual case of a primary squamous carcinoma which healed itself. They had had a somewhat similar case once before in which, however, the spontaneous healing was surmised but not seen as the growths were surgically excised. In the reported case a young man presented multiple lesions which had been in existence for seven years. In all that time there had been no metastasis. Sections of tumors in the early stages showed a highly malignant looking condition. Sections taken later in the disease showed an increased differentiation of cells and more complete cornification of the pearls. Finally there was healing with scarring. The writers believe that such cases as these may not truly be cancer, yet, in their early stages, they cannot be differentiated from it, either histologically or clinically.

In the field of roentgentherapy, investigation still continues as to when it can be used to the best advantage and as to method. More and more articles are written to prove that in certain types of carcinoma the reason for the failure to cure is inadequate irradiation. Hintze²⁶ is one of the more recent writers on the subject. He reports his observations on seventy-one cases of what he calls persistent carcinoma, that is to say, cases which five years after treatment by surgery or irradiation have not become free from symptoms or, having been free for a time, have relapsed. Thirty-nine of his cases had been treated first by surgery and thirty-two by irradiation. Sixty-two of the seventy-one cases were on the face. Four cases had been

treated exclusively by surgery Hintze calls attention to the fact that not one had been cured by this method. On the other hand, of thirty-five patients who had first been treated by surgery and then by irradiation nineteen were cured. Of seventeen patients who were treated by irradiation in other clinics one case was cured by surgery and four by irradiation in his own clinic. Of fifteen patients who were treated first by irradiation, in his own clinic, nine were not cured because there were multiple lesions. In six of the fifteen the primary focus persisted or relapsed. Under later treatment in his clinic eight of the nine multiple cases were subsequently cured. Two of the relapsing cases had been treated by the old method of small doses and one by medium doses. Not one had received a large dose at the very first treatment. These figures cause Hintze to say that the reason that carcinoma persists after irradiation is that the primary dose has not been large enough.

Hintze's conclusions would seem to be at variance with those of Dr. Frank.⁷ Reporting to the Vienna Society for Roentgenology Frank gave the details of his investigation. The carcinomas were large and of the pavement epithelium type. "Half of the tumor was irradiated with one large dose (1800 roentgens) while the other half was irradiated daily with a so-called fractional dose of 200 roentgens until a total of 4000 roentgens had been reached. The quality of the rays and the roentgen minute dose were the same. By the time 1000 roentgens had been administered to the side that had been given the fractional irradiations, a considerable decrease in the size of the tumor was noticeable, while the side to which the single large dose had been given showed no macroscopic signs of a change in spite of the fact that the surrounding skin, which had been exposed to this irradiation reacted noticeably. When 1800 roentgens had been reached, the same dose that the other side had had, the tumor had largely disappeared on the side irradiated with the small doses, while on the other side macroscopic changes were still lacking. In the further course it was observed that on the side to which the single large dose had been applied the tumor was still partly in evidence while it had completely disappeared on the side to which the fractional doses had been applied. Histologic studies revealed that on the side of the fractional irradiations the tumor cells were destroyed by undergoing cornification and maturation while on the side of the large dose a vacuolizing degeneration took place. Studies conducted in several other suitable cases led to the same results. In view of these observations Dr. Frank formulated the thesis that the application of a single large dose leads to a less rapid disappearance of a tumor than the fractional irradiations. This factor is important

when the danger of metastasis is considered, for it has been assumed erroneously that in cases of fractional irradiation the danger of metastasis is greater." Among the listeners to his report many agreed that fractional irradiations are generally to be preferred.

TUBERCULOSIS

The controversy as to whether erythema nodosum is of tuberculous origin goes on with unabated energy. The debate is still indecisive with, however, the weight of evidence favoring the negative side. No one has yet reported a respectable number of cases, a number large enough from which to draw many conclusions, nor has any one as yet put together all reported cases to make up an impressive total. In our search we find many papers based on one case and but one on as many as thirty.

As examples of the papers of the proponents we have chosen those of Moritz and Lederer,⁸ Deaquer and Aguirre.⁹

Moritz and Lederer⁸ imply rather than say that they believe the erythema nodosum is due to the tubercle bacilli. They base their opinion on a comparison of the capillary changes in erythema nodosum and in positive tuberculin test tissue. They found that in fifteen cases the changes were identical in the disease and in the test.

Deaquer^{9a} must also be classed with the proponents although he reports but one case. A woman, aged twenty-nine, had been in contact with a tuberculous sister for six months. An x-ray of this woman showed the picture of an acute disseminated tuberculosis. Occasionally she had a slight rise in temperature. The only other sign she had which pointed to tuberculosis was a well-developed erythema nodosum.

Aguirre^{9b} reporting a series of only eight cases, draws the very definite conclusion that "the results of his work, by which the presence of tubercle bacilli in the erythematous nodules was verified, constitute the most complete bacteriological proof of the tuberculous origin of erythema nodosum." He reports that in five cases out of eight, material from the erythematous nodule yielded the tubercle bacillus on culture. The material in one of the three negative cases was taken from the nodule by biopsy fifteen days after the appearance of the nodule. The material in the second negative case was taken from a guinea pig which had been in contact six months previously. The investigation was halted in the third negative case because of infection among the animals.

Opposed to these writers are the opinions of Lemming,¹⁰ of Nobecourt and Ducas and of Goldberg Curth.

Lemming¹⁰ reports thirty cases of erythema nodosum all of which occurred in patients with a past history of tuberculosis and nineteen cases

of recurrent erythema nodosum. As a result of his studies he concludes that the disease is an allergic expression of an active tuberculous infection. According to him, the presence of active tuberculous disease should be ruled out by careful examination. Erythema nodosum, he elaborates, may be the exogenous reinfection with the tubercle bacillus. It may be a superinfection or it may be present as a result of a grave active pulmonary tuberculosis in which the deficient antibody formation results in a state of anergy.

Nobecourt and Ducas³² believe that the erythema nodosum lesions in a case of theirs were the result of a hyperallergic state in spite of the actual evidences of tuberculous foci in the patient. The father of the patient had died of tuberculosis. On the patient herself the tuberculin test was positive and injections of her blood into a guinea pig gave rise to tuberculosis of the inguinal glands.

Goldberg-Curth³³ does not dispute that erythema nodosum is often seen in association with positive tuberculin reaction tests and even with clinical and roentgenologic signs of pulmonary tuberculosis. Extrathoracic tuberculosis is a rather rare accompaniment of erythema nodosum, she writes. She prefers to say of erythema nodosum that it is a cutaneous reaction to an infection whose pathogenic organism is unknown. She says further, that symptomatic erythema nodosum may develop in the course of nearly every infectious disease and as a cutaneous reaction to toxic substances. She admits that, in childhood, the majority of cases, not all, are closely related to a tuberculous process. As to the demonstration of tubercle bacilli in the blood or in cultures made of material taken from the nodules she does not admit that these are definite proof of the tuberculous nature of erythema nodosum. (Compare Aguirre above.) She does think that all forms are an indication of an allergic change in the organism. In short, she rejects the hypothesis that erythema nodosum is a true form of tuberculosis but agrees that cases do occur, although rarely, which present the clinical aspect of erythema nodosum and the histopathologic aspect of tuberculid.

The same reasoning which we have just seen applied to prove that erythema nodosum is or is not a tuberculous process we also see applied to prove that other diseases which occur more or less frequently in association with admitted tuberculosis are themselves tuberculous. For instance, Dr. D. W. Montgomery publishes³⁴ a case of lichen scrofulosorum which occurred coincidentally with lupus erythematosus. The latter occurred in close proximity to typical lesions of the former. This, he believes, indicates more than mere coincidence. Therefore, as lichen scrofulosus is admitted to be tuberculous the deduction is justified in this case,

he declares, that the lupus erythematosus is also tuberculous.

MacKee and Sulzberger³⁵ have published an interesting article on one of the rarer forms of tuberculosis, the rosacea-like tuberculid of Lewandowsky. This form has been known in Europe for some time but has apparently escaped recognition in this country. It differs from rosacea in that it has a tuberculoid structure and is essentially papular, but it resembles rosacea in that it shows erythema and telangiectasia although in lesser degree. The writers report that the subjects of the disease are very sensitive to quantitative intradermal injections of tuberculin. The disease responds well to injections of gold and sodium thiosulphate, to a high vitamin diet, general tonics, generalized irradiations of ultraviolet light and to intradermal injections of tuberculin. Hence it is important that this disease should be distinguished from rosacea which it resembles.

Wile and Grauer³⁶ report five cases of the same disease all of which were in women. Histologically, the changes were, in every instance, tuberculous. Some cases presented a state of anergy. Wile and Grauer believe that the disease is a true tuberculosis of the skin and is the end result of a hematogenous spread from an underlying focus.

TREATMENT

The number of reports having to do with the treatment of disease have been so numerous during the past year as to give the impression that more attention is being paid to this important field. Then too, the wide range and great variety of diseases considered are striking.

In our last report of Progress (*New Eng J Med* 211:1200 [Dec. 27] 1934) we noted that trichophytin was advocated for the treatment of dermatophytosis. Now we note that Traub and Tolmach³⁷ are not so enthusiastic about it as the earlier reporters. They studied the effect of trichophytin in 135 cases of dermatophytosis, the majority of which at the time of treatment were accompanied by dermatophytids. Fungus infection of the skin accompanied by the latter should, according to immunologic concepts, offer the most ideal means for evaluating trichophytin. The authors obtained fourteen cases of apparent cure. Some of these presented an early recurrence, in some the cure was questionable. There were varying degrees of improvement in fifty-eight cases. In sixty-three there was no change at all apparent. In those cases in which no improvement was obtained with the treatment, the application of salves such as Whitfield's ointment, etc., was followed by results. The authors conclude that trichophytin exerts little if any effect on the course of trichophytosis.

So, too, we find that dermatologists are awake

to the newer results in other fields of medicine Pusey and Rattner¹⁸ describe a dermatosis which closely resembled discoid lupus erythematosus in which they used organotherapy. It occurred in a woman and became especially pronounced with the menses. Based on evidence indicating that the adrenal cortex has a decided influence on the gonads 2 grains of desiccated whole substance (adrenal) was given tid. Improvement of the lesions followed and the exacerbations during the menses were no longer apparent.

Sézary and Horowitz¹⁹ report their investigation of the therapeutic effect of an ovarian extract mixed with the patients' own blood. The extract is added to 20 cc of blood and is injected intramuscularly three times a week until a total of twelve injections has been given. That they called a course. Sometimes they administered as many as three courses. Their best results were obtained in subderma which had appeared in patients who were approaching the menopause. One case entirely recovered. Five cases gave varying results.

The present day attitude relative to the value of gold and of bismuth in lupus erythematosus therapy is well represented by Smith.²⁰ For purposes of comparison he divided his twenty-four patients into two equal groups. One group received the gold therapy and the second group the bismuth. Then he compared the results. Gold cured more than bismuth but bismuth improved more cases than gold. Bearing these results in mind he selects bismuth as his choice because it is less toxic, less expensive and less inclined to light up or aggravate an existing tuberculosis.

Gouin and Bienvenue²¹ reported the result of their rather new technique in using gold salt therapy in cutaneous tuberculosis which they employed in nine cases of disseminated lupus, two of lupus verrucosus, six of tuberculous ulcers and three of tuberculous adenitis. First the lesions were opened by curettage, so that they could be subjected to the action of light and air. Each time that an injection of gold was given the lesion was scraped under anesthesia unless meantime the lesion had cicatrized. Under this method they found that five or six injections of 0.15 Gm gold sufficed to effect a cure.

MacKee and Cipollaro²² have made an important addition to the precautions to be taken in roentgenotherapy by calling attention to the general lack of a uniform, standard unit of measurement among roentgenologists. They advise the use of a Victoreen dosimeter and of reference to its unit as a "roentgen." Where as today it is common to refer to the various factors in an epulating dose, for example as 2 min, 3 ma 100 kilowatts distance 8 if the "roentgen" unit method were used the simple statement that the dose was one of 300 roent

gens would include all these factors. They give as another sample a patient who is said to have received one quarter of a unit. MacKee and Cipollaro would have the dose described as one of 75 roentgens. The adoption of such a unit as the "roentgen" would make for accuracy of description and also for clarity.

One of the most obstinate and at the same time alarming mishaps which the roentgenologist has to treat is a Roentgen ray dermatitis. Craps and Alechinsky²³ report a method of treatment which they say, is simple to use and which gives quick results. They tried their method on five patients in all of whom the response was good. First, they cleanse the affected area with ether and also remove all squamæ and crusts. Then they paint on a 5 per cent aqueous solution of silver nitrate. Now the whole is irradiated with a quartz lamp at a distance not greater than 20 cm for from five to ten minutes. This should be sufficient to dry the affected area completely and to make the nitrate turn a deep black. If it is not a glistening black, the painting and drying must be repeated. A dry sterilized gauze dressing is all that is needed to cover the area. Ointments must not be used.

Carty²⁴ is convinced of the superiority of the elastic adhesive plaster over all other methods in the treatment of bed sores. He declares that by this method, he can heal a bed sore in fifteen days. He takes two pieces of elastic adhesive pieces an inch wider than the sore. These he puts on the ulcer, overlapping its edges, one above the other. The dressing is left in place until it comes away of itself when, after wiping away any discharge present on the surface of the ulcer, it is replaced.

The treatment of warts still intrigues the medical mind. Shellow²⁵ has treated ninety-seven lesions in seventy-three patients with local injections of a 15 per cent solution of bismuth sodium tartrate. The wart is first cleansed with soap and water and then with iodine and alcohol. With a fine hypodermic needle from $\frac{1}{2}$ to 2 minims of the bismuth tartrate solution is injected from the side into the base of the wart. In from one to three days a dark hemorrhagic spot is visible through the keratotic area. At the same time the pain in the lesion if there was any disappears as does the peripheral redness. In fourteen to seventeen days after the injection the wart has flattened, the hard keratotic tissue has been thrown off and a smooth healthy surface has resulted.

Cornbleet²⁶ has reported very favorably on the effects of maize oil administered by mouth to patients with eczema. By eczema they mean a condition which started in infancy and has persisted ever since with exacerbations and remissions. This condition they say, is usually referred to as allergic, exudative and diathetic.

eczema, Darier's prurigo or generalized neurodermatitis. They consider the results unusually good. A few patients had asthma as well as eczema and the asthma was benefited as well as the eczema. The results seem permanent, for there have been but few relapses during the four and a half years they have been using the oil. Some patients who have had eczema since infancy have remained well for three years or more. The oil is administered by mouth and preferably chilled a little to make it more palatable. At first the dose is one tablespoonful taken before or after meals. Gradually the dose is increased until the patient is taking four tablespoonfuls three times a day.

Nichols writes⁴⁷ that by his method more than 80 per cent of the cases of acne in adolescent children can be controlled if their cases are seen early. The method consists chiefly of keeping the skin rather chapped by the use of soaps, at first mild but later stronger, and of whitewash of increasing strength. At bedtime the face is washed with mild castile soap and fairly hot water. Then the skin is sopped for five minutes with lotio alba, one-fourth strength, which is allowed to dry on and remain overnight. As the skin becomes accustomed to the treatment, the strength of the soap and the wash is gradually increased. If the skin becomes overdry the treatment is suspended for a few days to allow it to soften. Graduated sun exposures and ultraviolet light irradiations are very helpful adjuvants to the treatment. Nichols reports that, in thirty-seven children out of forty-seven the acne is virtually invisible or is well under control after treatment of from three months to four years.

The results with germanin (Bayer 205) in the treatment of pemphigus do not seem very encouraging. Its employment in pemphigus is said to rest upon the remedy's successful use in trypanosomiasis and upon the alleged resemblance of trypanosomiasis to pemphigus in that both are chronic, both have remissions and both have fever. It is stated by Tobias⁴⁸ in an article on "Juvenile Pemphigus" that many cases which at first showed a remission or an improvement later developed a recurrence and died. Other cases developed an exanthem and nephritis. The drug is given intravenously in a beginning dose of 0.3 Gm. which is gradually increased to as high as 1 Gm. After five doses a course has been completed. Tobias reports the case of a girl, five years old, who received the drug. She presented a definite improvement with the first course. A recurrence necessitated a second course. The child developed a septicemia and died.

Craps and Alechinsky⁴⁹ report a rather unusual treatment of such cutaneous lesions as a trophic ulcer, an infected traumatic ulcer, varicose ulcers, ulcerated syphilitic gumma and an

ulcer resulting from the curettage of a large tuberculous verrucous lesion of the palm. For the treatment of these various types of ulceration they used direct applications of an aqueous solution of histidine, 1:1000, made daily. In general, the ulcers became clean very rapidly and soon took on a good color. The skin tolerated the histidine well.

Beerman and his associates⁵⁰ call the attention of dermatologists to Dioxanthanol 1-8 as a substitute for chrysarobin. The drug was introduced into dermatology in 1916 under the trade name of "Cignolin".

The Council on Pharmacy and Chemistry of the American Medical Association says of it⁵¹ that it is made by the reduction of dioxanthraquinone, an easily available substance used in industry and gives as its formula, $C_{14}H_{10}O_3$. The formula for chrysophanic acid, which it is proposed to displace with dihydroxy-anthranol, is given as $C_{17}H_{10}O_4$. The manufacturers have suggested "Anthralin" as a name for the drug and this name has been accepted by the Council.

Anthralin is described as "a yellowish, crystalline powder, practically insoluble in water but readily soluble in the more complex and lipid solvents—a feature of distinct advantage in the preparation of ointments, lotions and pastes. Its color is probably least noticeable in petrolatum album which provides for it an economical and satisfactory ointment base." Anthralin has been used only for external applications in concentration of from 0.1 per cent to 5 per cent. A very weak concentration is always used first to test out the patient's tolerance. That discovered, the strength of the application is gradually increased.

Beerman, Kulchar, Pillsbury and Stokes⁵⁰ have used Anthralin in a great variety of diseases but with especial satisfaction in psoriasis and in mycotic affections. They state that the safe effective range of concentration is from 0.1 per cent to 1.5 per cent. Most of their results were obtained with 0.5 per cent although it was occasionally necessary to raise the strength to 1 per cent. A 2 per cent preparation has been known to produce a severe dermatitis occasionally. "The advantages claimed for dioxanthanol 1-8 include the following: 1. Definite chemical composition and economical synthesis from an available material. 2. Effectiveness in very low concentrations (from 0.1 to 2 per cent). 3. No constitutional symptoms such as renal irritation in these low concentrations. 4. Limitation of dermatitis—inducing action to the area of application without tendency to extension or generalization. 5. No production of conjunctivitis even when used on the face or scalp. 6. Comparatively little discoloration of clothes or skin and practically no discoloration of hair in the concentrations employed."

Beerman's report of the use of Anthralin on the scalp is very striking. Of twenty nine cases eighteen underwent complete involution, fifteen within five weeks.

On the body it was rarely necessary to use a concentration stronger than 0.5 per cent and treatment was usually begun with a 0.1 per cent. Complete involution was obtained in twenty three cases within four months, sixteen of them within five weeks. Other cases were improved from 40 to 90 per cent in a comparatively short time in three months or less. Only one case was entirely resistant.

The list of other diseases in which Anthralin has been successfully used is long and improving. Especial attention should be given to its success in combating mycotic diseases. Indeed a number of Europeans are quoted as believing that it is in this field that Anthralin finds its greatest usefulness. Beerman and his co-workers, however, rate its usefulness in psoriasis first and in mycoses second.

In conclusion, they say that "Dioxyanthralin is not proposed as a new drug nor one completely free from the objections familiar in the use of chrysarobin. It is none the less, we believe, a superior substitute which deserves greater popularity now that it can be made readily available in this country."

ANTE MORTEM AND POST MORTEM RECORDS AS USED
IN WEEKLY CLINICAL-PATHOLOGIC EXERCISES

FOUNDED BY RICHARD C CABOT, M D

TRACY B MALLORY, M D, *Editor*

CASE 22021

PRESENTATION OF CASE

A forty-two year old white American was first seen complaining of chest discomfort

The patient had always led a fairly sedentary life until about ten months previously. At that time he began to indulge in boxing and tennis as a means of exercise. Shortly thereafter, while playing tennis, he noticed that he would feel discomfort across his chest, equally distributed on both sides and not radiating. This was associated with a sensation of fatigue in both arms to the elbows. There was no breathlessness or palpitation. The discomfort subsided spontaneously after a minute or two and he never discontinued activity because of it. During the succeeding four or five months he suffered from similar attacks twice daily, particularly when walking uphill. These subsided promptly after resting for a few seconds. He consulted a physician who found no abnormality. An electrocardiogram was negative. Thereafter he continued to have recurrent attacks with moderate exertion but noticed that he was more prone to have them shortly after heavy meals and smoking. He lessened the amount of tobacco used from six to ten pipefuls daily to one and a half. This appeared to diminish the frequency of the attacks, and activity which had previously caused distress no longer did so.

His father died suddenly of heart disease at the age of fifty. His mother was living and had pernicious anemia.

At the age of ten he had had scarlet fever which was believed to have affected his heart.

Physical examination showed a well-developed and obese man who did not appear ill. There was very slight arcus senilis. The hair was partly gray. The pupils were equal and reacted normally to light and distance. The left border of cardiac dullness extended to, and the apex impulse was felt eight centimeters from the midsternal line in the fifth interspace. The right border was at the sternal margin. The sounds were regular and there were no murmurs. The pulse was 72. The peripheral arterial walls were soft. The blood pressure was 130/85. The lungs were clear. The edge of the liver was felt at the costal margin. Knee jerks were absent.

An electrocardiogram was normal.

X-ray examination of the chest showed normal heart contours. The aorta was normal in width but the knob was considered slightly prominent for his age.

The patient was advised to limit his activities and to continue his limitation of tobacco, using the occurrence of symptoms as a criterion. One month later he reported that he was completely relieved of chest discomfort. Thereafter he suffered distress occasionally but only with over-exertion.

About one and a half years later while indulging in moderate but not unusual exercise he suddenly fell unconscious and died shortly afterward.

DIFFERENTIAL DIAGNOSIS

DR HOWARD B SPRAGUE With no more than the ordinary mental reservations that one makes in cases of this sort I should say that Dr Mallory was playing ball with me this time.

To summarize, we have a relatively young man who has always led a sedentary life but suddenly decides he must have exercise and goes in for boxing and tennis. Shortly thereafter he finds that tennis brings on a sensation of discomfort in the chest and fatigue in the arms and he finds beyond that that exercise such as walking uphill also brings on the sensation. So far as I know, that sensation is angina pectoris. He consults a physician who examines him and finds a negative electrocardiogram and a physical examination which is not very significant. He has a rather bad family history in that his father died suddenly at the age of fifty but other evidence pointing to cardiac disease is very slight. There is a note that he has very slight arcus senilis. We always mention the occurrence of that sign but you can get any sort of figures that you want indicating that arcus senilis has something to do or nothing to do with arteriosclerosis. It has been thought by some to be associated with a certain type of individual with hypercholesterinemia and to be associated with arterial changes. I, myself, must confess that I am impressed when finding arcus senilis, perhaps particularly at this age. There is a little prominence of the aortic knob. He is said to be obese but the physician was able to find the apex impulse of the heart which means that the patient was probably not very obese or that the examiner was particularly dextrous.

The patient himself noticed that reduction of activity and reduction of tobacco had some effect in increasing his ability to exercise without discomfort and in this clinic I think our feeling is that tobacco in cases of angina pectoris should be reduced or omitted if possible. That feeling is not held so strongly by some other clinics.

The patient gets along very well and a year and a half later, indulging in moderate exer-

cise, becomes suddenly unconscious and dies shortly after, meaning that there may be a slight delay between collapse and death. Suddenness after all is a relative thing.

Dr. TRACY D. MALLORY: The interval was less than five minutes.

Dr. SPRAGUE: He has no evidence of valvular disease or lues. The knee jerks were absent but with the presence of active pupils I think that is not of any particular importance unless we go into the details of whether reinforcement was tried and so forth.

I am not going to do anything but mention the routine possibility of dissecting aneurysm which comes up at every case. I do not believe he had that. He died of angina pectoris. He died so suddenly that there would not be a sudden infarct, but just what we shall find in the coronary circulation, I do not know. He undoubtedly had advanced coronary disease but whether diffuse or localized in one of the main arteries or ramifications I cannot tell. I do not know that we can say actual occlusion of a coronary artery will be found because apparently recent unpublished evidence of Dr. Robert Levy of New York seems to show that the finding of actual occlusion of the coronary artery in death of this sort is the exception rather than the rule. The patient died from a coronary spasm or the result of coronary insufficiency leading to a standstill of the heart or possibly to ventricular fibrillation, so that I think the diagnosis is arteriosclerotic coronary disease, with death from angina pectoris and possibly with coronary occlusion as the terminal event.

CLINICAL DISCUSSION

A PHYSICIAN: Will you say a word about the normal electrocardiogram?

Dr. SPRAGUE: Unhappily, about twenty per cent of patients who come to our clinic with the symptom of angina pectoris have entirely negative findings,—electrocardiogram, physical examination, x-ray and the rest.

Dr. PAUL D. WHITE: One of the points of special interest in this case was the relationship of his symptom to tobacco. He himself thought that he had "tobacco angina" and hoped that that would be our diagnosis and that he might be passed for life insurance. Probably one should not make such a diagnosis as "tobacco angina." Although tobacco undoubtedly has an important influence in some individuals and aggravates their angina pectoris, it cannot alone be blamed for the angina pectoris in this man. The final result proved that.

The first instance of electrocardiographic proof of a specific effect of tobacco on the coronary circulation that I have had any knowledge of was handed to me by Dr. Starr of Hartford, Connecticut, a year or two ago. He is here and I wonder if he will say a word about that case.

Dr. ROBERT STARR: That case was a boy

about eighteen years old who had used tobacco for perhaps two years previous to the time I saw him. Two or three months before I saw him he was in training for basketball, injured himself, gave up training and went back to smoking and noticed that cigarettes after the intermission always made him dizzy. He was sent to me by Dr. Kingsbury, who examined him because of this dizziness and found the physical examination to be essentially negative. The blood pressure was normal, everything was normal. I took an electrocardiogram before he smoked, then had him smoke a cigarette and repeated the electrocardiogram, and when the records were developed they showed a very definite negative T wave after smoking. I asked him to come back and on the second visit I started the electrocardiograph going just before he began to smoke, every ten seconds or so I would take a tracing and it was evident that the T wave became negative at the time of his dizziness and returned to normal afterwards.

Dr. MALLORY: I think that is a very interesting observation. So far as the peripheral arteries are concerned the effect of tobacco is very obvious. Cases of Buerger's disease and Raynaud's disease usually show very marked increase in spasm during and for a considerable period following smoking.

Dr. WHITE: Stimulated by this observation of Dr. Starr's we have begun a study which is now in progress, on the effect of the inhalation of tobacco smoke on the electrocardiograms of normal individuals and of those with coronary disease or angina pectoris, there have been some definite changes but not so striking as in Dr. Starr's original case. The rapid inversion of the T waves in lead two in that case makes us believe that certain individuals doubtless have a special coronary sensitivity to tobacco with spasm, it may prove worth while to test individual cases in the laboratory by electrocardiography to see if there should be a reduction or complete omission of tobacco in their treatment. We shall make a full report of this study at a later date.

CLINICAL DIAGNOSIS

Coronary heart disease.

Dr. HOWARD B. SPRAGUE'S DIAGNOSES

Arteriosclerotic coronary disease
Angina pectoris as the cause of death
Terminal coronary thrombosis unlikely

ANATOMIO DIAGNOSIS

Coronary sclerosis, marked
Acute atheromatous Aorta mitral valve
Myocarditis, fibrous

PATHOLOGIC DISCUSSION

Dr. MALLORY: The postmortem examination on this case showed what Dr. Sprague predicted.

ed There was a very severe grade of coronary sclerosis present throughout all branches of the coronary arteries but most marked in the descending branch of the left which was reduced to barely one-tenth of the normal diameter. There was no thrombosis. The blood was fluid throughout all the vessels, and I would second the point that Dr. Sprague made that relatively sudden deaths rarely show coronary thrombosis. They always show diseased coronaries but there is no complete obstruction. In other words it definitely is an anginal death and not a death from coronary thrombosis.

He showed rather more than the average amount of arteriosclerosis in the aorta and some of the other organs. The heart was not hypertrophied. On section we could make out grossly minute areas of scarring, one or two millimeters in diameter, scattered throughout the myocardium but definitely most numerous in the region supplied by the descending branch of the left coronary. Microscopically this was confirmed by finding small areas of fibrosis where the muscle cells had entirely disappeared. These were evidently quite old, however, and there was no sign of any fresh, recent degeneration of the heart muscle. The case was checked with examination of the head, where nothing that would explain any acute death was found.

CASE 22022

PRESENTATION OF CASE

First Admission A forty-nine year old Polish landscape gardener entered complaining of difficulty in breathing and "turning black" for two weeks.

Twenty years before entry the patient began having asthma every winter beginning about the fifteenth of November and lasting off and on until the following May. The attacks never occurred at night but seemed to be precipitated by cold air. They usually were associated with cough and the production of small amounts of blood-tinged sputum. There was no past history of any other allergic manifestations. Two and a half years before admission he had a chest cold associated with a marked coryza. He coughed considerably with the production of a slightly blood streaked thick mucoid sputum. He remained at home and recovered in about two to three weeks. Since then he became increasingly dyspneic, especially upon climbing stairs. He also developed slight blurring of vision, occasional headaches, tinnitus, and vertigo. One year before admission he noticed that his face, lips, cheeks, and fingers were bluish. Five months before admission he again developed a chest cold, entered a hospital, and was told there that he had a blood disease. A pint of blood was withdrawn following which he felt worse and was put into an oxygen tent. He left the hospital after three weeks and re-

turned to work. His shortness of breath continued but was not so severe. Two weeks before admission, after a slight cold, it became almost impossible for him to breathe, expiration being especially difficult. He had marked dyspnea even on walking very short distances and felt exhausted all the time. There seemed to be a constant pressure in his chest, as if he were being squeezed. He noticed that his hands, especially his fingers, and his face and lips were becoming very blue and at times suggested a real black color. He experienced cramps in the calves of his legs upon the slightest movement. His ankles became slightly swollen. He wheezed considerably and a fairly marked degree of orthopnea developed. During the past five months he lost about fifteen pounds in weight. Recently he had been taking two glasses of whiskey every night which he believed had helped his condition.

His mother had asthma.

The past history is negative, except that five years before entry he had worked one summer with broken rocks in building a road.

Physical examination showed a well-developed and nourished man lying in bed in no apparent distress. His breathing was abdominal in type. There was marked cyanosis of the lips, face, hands, and feet. The mucous membranes were highly colored, the fundic veins were very dark. There was marked pyorrhea. The tonsils were slightly enlarged and highly colored. There was slight dorsal kyphosis. The chest was barrel shaped and the motions were scarcely perceptible during inspiration. The lower chest wall was drawn in with inspiration. Scattered over both lung fields were numerous crackling râles. The breath sounds and tactile fremitus were diminished. The heart was not enlarged to percussion although the right border was 4 centimeters from the mid-sternal line. No murmurs were heard. The blood pressure was 134/80.

The temperature was 99.2°, the pulse 88. The respirations were 15.

Examination of the urine was negative. Examination of the blood showed a red cell count of 7,990,000, with a hemoglobin of 120. The white cell count was 11,000, 81 per cent polymorphonuclears. The stools were negative. The vital capacity was 600 cubic centimeters and after adrenalin 1200 cubic centimeters. Other determinations showed a vital capacity of 1,000 to 1,200 cubic centimeters before adrenalin and 1,300 to 1,700 cubic centimeters after adrenalin.

X-ray examination of the chest showed an enlarged heart both to the right and left of the spine and prominent lung markings.

He improved subjectively somewhat on ephedrin and potassium iodide and was discharged twelve days after admission.

Second Admission, six months later.

During the interval he did fairly well, continuing with ephedrin and potassium iodide,

and had not been completely incapacitated Six weeks before admission his asthma became worse and he was forced to take adrenalin almost every day for relief. He gradually became more fatigued and his legs much weaker. Two weeks before entry, after some light work he was forced to go to bed. His cough increased and one week before entry he coughed up a slight amount of bright red blood with his sputum. He believed that his cyanosis had increased slightly during the past two weeks.

Physical examination was similar to that of his previous admission. The liver was felt two fingerbreadths below the right costal margin. There was slight clubbing of the fingers.

Examination of the blood showed a red cell count of 6,740,000, with a hemoglobin of 100 per cent and a white cell count of 6,700. 69 per cent polymorphonuclears. The oxygen capacity was 25.0 volumes per cent. The volume of the cells was 66.1 per cent. The volume index was 1.27, the color index 1.06. The vital capacity was 700 cubic centimeters. The nonprotein nitrogen of blood was 53 milligrams per cent. The serum protein 6.1 per cent.

His condition remained unchanged. He continued to have some bloody sputum. His skin was blue and almost black. X-ray examination of the chest showed slight fibrosis with no evidence of mediastinal tumor. He continued to fail gradually and died about two weeks after admission.

DIFFERENTIAL DIAGNOSIS

DR. FRANCIS M. RACKEMANN "Five months before admission he again developed a chest cold, entered a hospital, and was told there that he had a blood disease." I assume that this blood disease was polycythemia. He came to the hospital with shortness of breath and with a marked bluish color all over. It is interesting to speculate a little. If it was a true polycythemia I think he should have been improved by the withdrawal of a pint of blood. Whatever it was he recovered all right. The shortness of breath continued but was not so severe. All this took place about five months before admission and during the interval he was working as a landscape gardener.

"He experienced cramps in the calves of his legs upon the slightest movement." I take it that that is a circulatory disturbance of the blood supply to his leg.

"The heart was not enlarged to percussion although the right border was 4 centimeters from the midsternal line." No doubt the heart borders were obscured by the tremendous emphysema.

The respirations were slow. Why were his respirations slow? Evidently because while lying in bed in no apparent distress, even in spite of his barrel-shaped chest and the evidence of emphysema, he was compensating at that moment and his breathing was easy.

The interesting feature in the physical examination at the second entry is that the liver was no farther down than two fingers, sometimes in emphysema it is down to the umbilicus. Clubbing of the fingers is also important. The record does not say whether the spleen was felt, as it might have been if the polycythemia was other than of the secondary type.

The oxygen capacity is above the normal. His blood was able to take up more oxygen than normal blood.

"The volume of the cells was 66.1 per cent. The volume index was 1.27." I take that to mean that the total volume of the blood cells was larger than normal, that all the cells together occupied a larger space and that each cell was a little larger in size than normal.

"The color index was 1.06." The cells contained a little more hemoglobin than normal.

It seems to me that this man with his story of trouble for about two and a half years undoubtedly has some sort of chronic infection in the chest which has led to the secondary formation of an emphysema and that he has a compensatory polycythemia, this time a quite marked grade and then as time goes on the condition seems to get worse and eventually there is a terminal failure of the right heart and the picture of a typical cor pulmonale. That is the obvious explanation of this picture. We should not rest, however, without at least considering the matter of polycythemia, because the red count was so high. It seems to me that the absence of relief from bleeding and the absence of enlargement of the spleen would tend to rule that out. The question of mediastinal tumor has been considered but as a matter of fact cyanosis was generally distributed, in the feet as well as the head and hands, and x-ray of course ruled it out anyway. Beyond that I do not think of any other state that would come in.

I believe that Dr. Mallory will find this man with a very marked emphysema which I believe will be what he calls anatomical emphysema as well. I think the alveoli will be broken down. The patient raised blood on frequent occasions. That is evidence of coalescence of alveoli and after it there will be thickening and evidence of congestion in the pulmonary circulation which in turn will cause a marked strain on the right side of his heart. I think that the sequence of events has occurred about in that order, that is, secondary infection first, emphysema second, polycythemia third, and strain on the heart fourth.

X-RAY INTERPRETATION

DR. AUDREY O. HAMPTON He had three or four x-ray examinations. At this first examination from that film alone we would be inclined to say the man had a big heart with passive congestion and some emphysema. There is nothing very startling in the anteroposterior view.

of the chest. I think we would not know definitely from looking at that film whether he had asthma or not. If we had a fluoroscopic note to go along with it, we probably would. It is surprising how little you see in that film. The lateral view is quite a different picture. The anteroposterior diameter of the chest is greater than the transverse diameter and all the blood vessel markings show this queer separation in the substernal area which suggests blebs. In this oblique view you see little but this cavity-like formation along the margin of the sternum.

At the second examination you get a little more definite impression that the heart is enlarged. There is a dilated pulmonary artery. In the oblique view the pulmonary artery has pressed upon the esophagus so that we can say it is enlarged, and then working back, from this fact we can deduce that the strain was on the right side instead of the left side of the heart. He probably had right-sided enlargement of the heart. I do not see any other good reason for saying that. The question of fibrosis, which we had in the other cases, does not seem to come up here and we can say that this is an acute process at the right base, pneumonia or pneumonia plus passive congestion. This film here exaggerates the heart shadow and probably gives you a better idea of the right-sided heart enlargement than the other film. We have a high right auricular curve here. The trachea makes quite a bend toward the right. I had not noticed that. I do not know just why that is. It does not seem to be displaced here. I suppose that is the oblique projection which makes it look that way.

A PHYSICIAN: I would like to ask about his blood Hinton. If the blood disease he had early were syphilis, I should think he might fit into the group of cardiac pulmonary sclerosis—so-called Ayerza's disease.

DR. TRACY B. MALLORY: I think it was negative, although I do not have the record.

CLINICAL DIAGNOSES

Asthma.
Emphysema
Secondary polycythemia
Cor pulmonale

DR. FRANCIS M. RACKEMANN'S DIAGNOSES

Asthma with secondary infection
Emphysema
Polycythemia
Cor pulmonale

ANATOMIC DIAGNOSES

Emphysema diffuse
Cor pulmonale
Polycythemia
Multiple petechial hemorrhages
Chronic passive congestion of the liver and spleen

Ascites, slight
Cholesterosis of the gall bladder

PATHOLOGIC DISCUSSION

DR. MALLORY: This is a case that has left me completely puzzled. He had a very marked cor pulmonale, the heart weighing 550 grams. The right ventricle came right down to the apex of the heart and was distinctly larger than the left ventricle. He had, as Dr. Hampton pointed out, an extreme degree of barrel chest, that is, increase in the anteroposterior diameter. The diaphragm was flattened and low and the liver and spleen pushed down. They were also a little enlarged with chronic passive congestion, as you would expect with right-sided heart failure, but they were much lower than they were enlarged.

The lungs were extremely voluminous and I was particularly impressed with the way in which the apices crowded up into the supra-sternal notch. On the autopsy table, when I first saw this man, I thought he certainly must have mediastinal tumor because at that time he showed intense congestion of the neck, face and arms, and none whatever of the lower half of the body, although cyanosis was previously noted on the waist in the lower half of the body. When we came to section these lungs, we could find very little emphysema in the sense of fusion of the alveoli. All the alveoli were uniformly dilated and possibly a little over-dilated. I think one has to say there is a slight diffuse emphysema but it is not at all the striking picture that I think one might have expected.

The pulmonary artery showed no sclerosis whatever. All its main branches and its small branches were dilated and only here and there microscopically can we pick up a little bit of atheroma and intimal thickening. The pulmonary veins likewise were dilated. There was no scarring in the lung. The bronchi showed no hypertrophy of the muscle and were perfectly free from exudate. So that from the point of view of the autopsy we have a barrel chest, an early stage only of emphysema but a very extreme grade of cor pulmonale such as you would expect only in the later stages of emphysema.

His bone marrow shows a very high grade of hyperplasia with an inversion of the normal ratio, ordinarily four white cells to one red. In this case the ratio is just about the reverse. It is perfectly consistent, however, with a secondary type of polycythemia, and I think that is probably what he had.

A PHYSICIAN: Was the spleen big?

DR. MALLORY: It was about 300 grams. That is ordinarily just below the limit of palpability, not particularly large, and he had enough passive congestion of his liver to account for that much enlargement in the spleen also.

NON APPROVED MEDICAL SCHOOLS

It is interesting to review the history of medical schools in America and to note certain trends and stages of development. In the Directory of the American Medical Association there is reference to over four hundred medical schools which have been chartered in what is now the United States. Of these, two date back to before the Revolution and three to before 1789. Although there has been a rapid decrease in the number of schools since 1910 to less than one hundred now in existence (including good, bad and indifferent) there was a far higher mortality in the last few years of the nineteenth and the early years of the twentieth century. Many of the schools were a mushroom growth, almost ephemeral and to the shame of American medical education, one often finds the comment "this school became fraudulent in its last years." It would throw light on one of the

baser sides of American life to have, what can not ever now be recorded an accurate description of the rise and fall of these so called medical schools.

Many of them were characterized as "proprietary", that is, they were operated for the benefit of a single proprietor or sometimes for a small group of owners. Their educational function was of slight importance, if any, and when the symbol of medical education, the medical degree was, as so often happens, mistaken for the reality of education itself, it became profitable to sell the degree without the education. The development of diploma mills in the United States was a marvelous growth difficult to understand after the lapse of years.

Such extensive hypocrisy and sham were bound to stir up reaction, and there developed fairly rapidly a sentiment in favor of protecting by governmental action under statute, the sick against the incompetent and the unscrupulous practitioners of the healing art. This double headed attack was only in part successful because the unscrupulous are not always technically incompetent, but very slowly public opinion has come to the support of measures calculated to eliminate the unqualified practitioner, whatever might be the cause of his disqualification.

Gradually organized bodies with varying degrees of authoritative opinion have given utterance to their judgments on medical schools hoping that the force of public opinion would accomplish what could not be effected by statutory enactment. The charter of a medical school may be revoked for fraud but not for mere ignorance and incompetence on the part of the teaching staff.

If however, the ignorance and incompetence are known, public opinion has an opportunity to work itself out. It is on this account that the so-called non approved schools are so secretive about their inner workings. The results of their educational procedures are well known; their graduates are not well educated. Just how they actually carry on their work they refuse to disclose and they refuse to permit official evaluating bodies to make surveys.

Occasionally one of these schools has gotten into court, by compulsion of course, because although they make great show of bringing suit against persons or groups who attack them, the thought of actual court inquisition causes them great uneasiness. Then the court record of what they have actually done reads like opera bouffe, and several charters have been revoked for fraud.

In Massachusetts fifteen medical schools have been chartered. Of those which have endured to the present time, some have kept pace with progress and have been modernized. Some are still in the Dark Ages. Why should Massachusetts

the commitment is civil it must be made to a penal institution,—namely, the State Farm in the case of men, and the Reformatory for Women in the case of women. An additional handicap exists in the fact that although a criminal commitment for drunkenness to the State Farm calls for a maximum of one year, a civil commitment to the same institution by reason of inebriety provides for a maximum of two years.

"It would be entirely logical for the General Court to authorize the care of the inebriates by the Department of Mental Diseases, as was the case prior to 1922. The mental hospitals of the State are however, at the present time crowded, with an average overcrowding of slightly over 17 per cent, and an annual net increase of about 460 patients under care is to be expected. Should the General Court, therefore, consider this change advisable it would be necessary to provide suitable buildings which should be located on the grounds of some institution with a large land area, as, for instance, the Gardner State Hospital, so that the patients committed could be kept separate from the insane and have an ample opportunity to work out of doors. The proper size of such facilities is entirely problematical; it seems clear, however, from the history of Foxborough and Norfolk experiments, that a separate institution is not warranted. On October 31, 1935, for example, there were only 17 male inebriates under commitment at the State Farm, and only 7 women at the Reformatory for Women. Although it is reasonable to suppose that some increase might be expected if commitments could be made to a hospital instead of to a correctional institution, there seems to be some reluctance on the part of the court to make use of the existing provisions of civil commitment. Unless and until the General Court finds it feasible to establish suitable facilities at some existing state hospital, no change in the existing law is recommended by your Commission.

MISCELLANY

AFFAIRS OF THE ACADEMY OF PHYSICAL MEDICINE

Dr Franklin P. Lowry of Newton was elected Secretary-Treasurer of the Academy of Physical Medicine recently by the Directors to fill the unexpired term of the late Dr Arthur H. Ring, who had held that office from 1931 to the time of his death.

Boston has been selected as the place for the Annual Meeting in October 1936. The Academy met last in Boston in 1930.

Members of the Program Committee for the Boston meeting are as follows: Dr William D. McFee, Boston, Chairman; Dr William Blerman, New York City,

Dr Ralph Pemberton, Philadelphia; Dr Grant E. Ward, Baltimore; Dr George Miller MacKee, New York City; Dr Francis P. McCarthy, Boston; Dr Groesbeck F. Walsh, Fairfield, Alabama.

CORRESPONDENCE

ARTICLES ACCEPTED BY THE AMERICAN MEDICAL ASSOCIATION COUNCIL ON PHARMACY AND CHEMISTRY

535 North Dearborn Street, Chicago, Ill.,
December 30, 1935

Managing Editor, *The New England Journal of Medicine*,

In addition to the articles enumerated in our letter of December 4 the following have been accepted:

Ledeile Laboratories

Antidysenteric Serum (Polyvalent) 20 cc vial package

Paike, Davis & Co

Mapharsen

Ampoules Mapharsen 0.04 Gm

Ampoules Mapharsen 0.06 Gm

Ampoules Mapharsen 0.4 Gm

Ampoules Mapharsen 0.6 Gm

Squibb Cod Halibut Liver Oil

Winthrop Chemical Co. Inc.

Ampules Suprarenin Powder, 0.05 Gm

The following product has been accepted for inclusion in the List of Articles and Brands Accepted by the Council But Not Described in N. N. R. (New and Nonofficial Remedies, 1935, p. 445):

The National Drug Co.

Smallpox Vaccine (Vaccine Virus)

PAUL NICHOLAS LEECH, *Secretary*,
Council on Pharmacy and Chemistry

RECENT DEATHS

MITCHELL—WINTHROP DODD MITCHELL, M.D., a retired surgeon, died at his home in Worcester, Massachusetts, December 30, 1935. He was born in East Orange, New Jersey, in 1862, the son of Aaron Peck Mitchell and Elizabeth (Dodd) Mitchell and was educated at Phillips (Andover) Academy and graduated in medicine from the Bellevue Hospital Medical College in 1887. He later studied in Vienna, Munich and Dublin.

He was formerly associated with several New Jersey hospitals, having served as Medical Director Emeritus of St. Michael's Hospital, Newark, New Jersey.

He was a Fellow of the American College of Surgeons, a member of the Worcester Club and the Tatnuck Country Club of Worcester.

A widow and a daughter survive him.

MURPHY—TIMOTHY JOSEPH MURPHY M.D., LL.D., of 372 Dudley Street, Roxbury whose office was at 120 Beacon Street, Boston, died January 1 1936 after a short illness.

He was born in 1866. Early in life Dr. Murphy was a reporter on *The Boston Herald*. After graduating from Boston College in 1888 he entered the Harvard Medical School and was given his M.D. degree in 1892.

He was chief of staff of Boston Sanatorium. Professor of Medicine at Tufts College Medical School and member of the Staff of St. Margaret's Hospital and had served as President and Censor of the Norfolk District Medical Society.

Dr. Murphy belonged to the Catholic Alumni Society, the Massachusetts Order of Foresters and Knights of Columbus.

He was recently appointed Medical Examiner of the M. C. O. F. In addition to the Massachusetts Medical Society Dr. Murphy was a Fellow of the American Medical Association.

Six children survive him.

MORRIS—GEORGE PATRICK MORRIS M.D. of 811 Broadway South Boston died January 4 1936 after a long illness. He was born in 1860. After his preliminary education at the Boston Latin School Dr. Morris entered Harvard College graduating therefrom in 1883 and from the Medical School in 1891.

He was a member of the South Boston Medical Society and a Fellow of the Massachusetts Medical Society and the American Medical Association.

Dr. Morris is survived by his widow Mrs. Katherine J. Morris, a son George P. Morris, two daughters Miss Mary G. Morris and Miss Eleanor L. Morris, two sisters, Miss Mary T. Morris and Miss Agnes C. Morris and two brothers Mr. Robert E. Morris and Mr. Charles H. Morris.

NOTICES

A LECTURE BY DR. E. V. MCCOLLUM

The Worcester County Home Economics Association is sponsoring a lecture by Dr. E. V. McCollum Ph.D., Sc.D., the noted research worker, author and lecturer at Johns Hopkins University on Friday evening January 17 at the Worcester Girls Trade School, High Street, Worcester. His subject will be Nutrition in Its Newest Phase. Tickets are seventy-five cents and may be obtained at Eastons, 46 Main Street, Worcester on or after January 10.

BOSTON DISPENSARY

25 Bennet Street Boston
Medical Conference Program
9-10 A.M. January 1936

Thursday January 9 — G. I. Clinic. Dr. H. S. Andrews.

Friday January 10—Recent Studies of Internal Secretion. Dr. Joseph C. Anb.

Saturday January 11—Presentation of Ward Cases. Dr. Jacob Schloss.

Tuesday January 14—Cases from Blood Clinic. Dr. Isadore Olef.

Wednesday January 15 — Modification of History Taking and Physical Examination Methods in Pediatrics. Dr. Francis McDonald.

Thursday January 16—Social Service Case Presentation. Miss Edith Canterbury.

Friday January 17—The Diagnosis and Management of Biliary Tract Disease. Dr. Frank H. Lahey.

Saturday January 18—Presentation of Ward Cases. Dr. H. C. Gordonier.

Tuesday January 21 — Diagnosis of Polycythemia. Dr. William Dameshek.

Wednesday January 22 — Some of the Newer Aspects of Cancer. Dr. William M. Shedden.

Thursday January 23—Allergy Clinic. Dr. Joseph Kaplan.

Friday January 24 — Some Aspects of Hemolytic Streptococcal Infection. Dr. Chester S. Heffer.

Saturday January 25—Presentation of Ward Cases. Dr. Heinz Nagendanz.

Tuesday January 28 — X-ray Demonstration. Dr. Alice Effinger.

Wednesday January 29—Pediatric Case Presentation. Dr. Francis McDonald.

Thursday January 30 — Case Histories in Brain Tumors. Dr. J. J. Skirball.

Friday January 31—The Heart and Aorta in Chronic Hypertension. Dr. Paul Dudley White.

MEDICAL CLINIC AND STAFF ROUNDS AT THE PETER BENT BRIGHAM HOSPITAL

At 3:30 P.M. on Thursday January 16 in the Amphitheatre of the Peter Bent Brigham Hospital Dr. Henry A. Christian, Physician-in-Chief, Harvard Professor of the Theory and Practice of Physics in the Harvard Medical School will give a medical clinic. To it are cordially invited practitioners and medical students.

On Saturdays in the wards of the Peter Bent Brigham Hospital from 10 to 12 staff rounds will be conducted by Dr. Christian.

LAWRENCE CANCER CLINIC

Established 1928

Lawrence Mass.,

December 30 1935

To the Physicians of the North Half of Essex County

Dear Doctor

The regular Lawrence Cancer Clinic, to be held at Lawrence General Hospital, 1 Garden Street, Lawrence upon Tuesday, January 21, at 10:00 A.M. will be a Demonstration Clinic with Channing C. Simmons, M.D. of Boston, Associate in Surgery in the Graduate Courses in Medicine at Harvard University Medical School, Surgeon in Chief to Col. H. P. Huntington Memorial Hospital, member of the Cancer Commission of Harvard University and Visiting Surgeon to Massachusetts General Hospital, Boston, present as consultant. You are invited to

accompany any of your patients whom you desire shall have this service, or to send them with a note, and a report will be returned to you. The service is gratis. Your attendance at the Clinic is always welcome.

This Clinic is endorsed by the Committee on Postgraduate Instruction of the Massachusetts Medical Society.

REPORTS AND NOTICES OF MEETINGS

HARVARD MEDICAL SOCIETY

The Harvard Medical Society met at the Peter Bent Brigham Hospital November 26, with Dr Henry A. Christian presiding. The first case was presented by Dr Lawrence E Putnam of the medical service. A twenty-nine year old native housewife entered one and a half weeks previously with the complaint of a cough of six weeks' duration. Between the ages of ten and fourteen years she was in a tuberculosis preventorium, because of a definite family history of tuberculosis. Between the ages of fourteen and nineteen years she lived with an aunt and three sisters. The latter have since developed active pulmonary tuberculosis. Her father and one other sister had had pulmonary tuberculosis. At the age of twenty-three years she suffered a "chest cold", with pleuritic pain in the right chest, and had afternoon fever as high as 102 degrees Fahrenheit. She stayed in a tuberculosis sanatorium for six months at that time. Five years ago at the age of twenty-four years she was married, and has since had two children without ill event or reactivation of the pulmonary disease. Six months ago an x-ray of the chest is said to have shown a "scar at the right apex". Six weeks before entry she developed pleuritic pain in the left lower chest, and one week before entry began to experience night sweats. On admission she had severe cough, dyspnea, and vomiting. Physical examination on entry was negative except for the lungs. There was dullness at both apices, greater on the right, and dullness in the left axilla and left chest anteriorly. There were numerous medium moist râles and diminished breath sounds over these areas. Urinalyses were negative. The hemoglobin was 85 per cent, the red blood count 3,900,000 to 4,500,000, and the white count 9,000 to 12,000 with 10 per cent monocytes. Four sputum examinations were positive for acid fast organisms. For the first three days after entry her temperature rose to ninety-nine degrees in the afternoon, since that time it had been normal. X-ray plates taken

the day after entry showed consolidation at the right apex, interpreted as tuberculosis, and a uniform consolidation at the left base, which was interpreted as bronchopneumonia. One week later the roentgenological picture remained the same, and the consolidation at the left base was interpreted as probably being of tuberculous nature.

Dr Christian commented on the fact that some six months ago x-ray studies had shown an apparently healed process, and that at recent examinations large numbers of tubercle bacilli had been found in the sputum. He raised the questions as to whether the apical or basal lesion was the source of the organisms, and what the significance of the basal lesion might be.

Dr Burgess Gordon spoke of the striking absence of signs of toxicity in this case. Many cases of tuberculosis with basal lesions have no symptoms except those suggesting pleurisy or bronchiectasis. They usually do not produce a positive sputum until late in the disease process.

Dr Lowrey F Davenport remarked on the change of attitude relative to pregnancy in tuberculous women. It is the present consensus that it is not the pregnancy itself, but the increased physical activity in the home during the first six months after delivery that is responsible for aggravating the infection. The advisability of aborting such women is now regarded with more conservatism than formerly.

Dr Robert Bates presented the surgical case. A forty-nine year old married male cabinetmaker, who was admitted to the hospital from Middlesex sanatorium for thoracoplasty. In 1914 he had had pleurisy on the right side. In 1917 he experienced hemoptysis and weight loss. In 1922 he suffered gross pulmonary hemorrhage, and was treated in the Rutland Sanatorium. Since that time he had numerous hemoptyses and hospitalizations. On admission to the Peter Bent Brigham Hospital he had an advanced fibrocaseous tuberculosis of the upper half of the right lung, with minimal lesions at the left apex. A two-stage thoracoplasty was performed on the right side, with the removal of the first nine ribs. Dr Harlan F Newton remarked on the fact that the patient had been treated for eleven years without active collapse therapy. The extent of the active process in the right lung without more involvement of the left is striking, and surgical measures must be approached carefully in such cases because of the danger of initiating a tuberculous pneumonia in the good lung. Dr Elliott Cutler raised the question whether such patients who are obviously a menace to society cannot be confined to sanatoria until their disease is at least quiescent. Dr Christian replied that the state had no such power over tuberculous patients.

Dr Christian introduced Dr Burgess Gordon, a former resident on the medical service at the Peter Bent Brigham Hospital, and at present associate professor of medicine at Jefferson Medical College, physician in charge of the department of chest diseases of the Jefferson Hospital, and visiting phys-

clan in the Pennsylvania Hospital Dr Gordon spoke on the "Mechanics and Effects of Abdominal Compression in the Treatment of Pulmonary Tuberculosis" His paper will be published in an early issue of this Journal

Dr E. S. Emery Jr in commenting on the paper remarked that the vital capacity and diaphragmatic excursion was less in athletes than in non athletes and questioned whether the vital capacity was a reliable measure of the pulmonary efficiency in any condition except cardiac disease

Dr Harlan F Newton stated that it was not the height of the diaphragm but the elimination of its pumping motion that was of importance in explaining whatever benefit might be derived from diaphragm immobilization

FAULKNER HOSPITAL CLINICAL MEETING

The regular monthly clinical meeting was held at the Faulkner Hospital on January 2 at 7:00 P.M.

One of the cases which came to autopsy during the preceding month was presented. This brought out several points of interest. The patient had chronic tuberculosis of the apices and tuberculous lesions in the cecum. During the World War this patient had had attacks of dysentery and the question immediately arose whether the dysentery at that time could have been due to tuberculous lesions. Apparently even at autopsy it is difficult to decide just how old tuberculous lesions are. This is an important point in regard to the question of compensation from the government. The next point was the fact that it is so difficult to find tuberculous bacilli in the spinal fluid. It is of course possible that in cases where there is an increased cell count and a pollicle formation there are no organisms in the spinal fluid but the reaction in the spinal fluid is the result of the lesions and organisms in the meninges. This patient turned out to have millary tuberculosis and the lesions in the meninges were millary tubercles. A most exhaustive search was made of several specimens of the spinal fluid and although a pollicle developed in some of the specimens no organisms were found. Another interesting point in this case was the clearing up of the spinal fluid by constant drainage. A needle was inserted into the spinal canal in the lumbar region and left there for four days, while constant intrathecal venous salt solution was given. The cell count in the spinal fluid diminished considerably during this drainage but as there was a diffuse millary tuberculous the patient naturally did not improve.

The next case reported was a patient with thrombocytopenic purpura in which the outstanding symptom was pronounced flowing from the uterine mucosa. It was felt at first that the case was one of some disturbance of the hormone of the anterior part of the pituitary gland. Eventually hemorrhage from the gastric mucosa developed and generalized purpura. The possibility of both conditions being present was considered. The blood platelets became

less and less in the blood and after the fourth transfusion disappeared quickly suggesting that some destructive process for blood platelets was active in the body. Hemorrhage eventually developed in one of the eyegrounds. The spleen was removed and during the three weeks after splenectomy no transfusions were needed and the red blood count returned to 4,500,000. The pathologist emphasized the fact that there is no definite pathology peculiar to this condition existing in the spleen. In the spleen from this particular case there was phagocytosis of erythrocytes and marked hyperplasia of the endothelial cells in the center of the lymph follicles and also enlargement of the lymph follicles. The therapeutic effect of splenectomy in these cases is one of the dramatic cures in medicine.

Dr Maurice B. Strauss then gave an excellent presentation of his work on anemias in pregnancy. He called attention to the fact that a Boston physician Dr. Walter Channing was one of the first ninety-five years ago to mention anemias in pregnancy. Dr. Strauss called attention to the fact that he was talking about a series of cases in which obvious causes for anemia were absent. In two thousand cases in which obvious causes for anemia did not exist 50 per cent of the cases showed a hemoglobin below 70 per cent. In this group the so-called ward cases showed a higher incidence than private cases. No apparent cause for the anemia is found. It is spoken of as hypochromic anemia and is looked upon as due to a deficiency in iron. Three possibilities present themselves:

1. Inadequate iron in the diet.
2. Gastric acidity or some defect in the secretion of the stomach which affects the assimilation of iron.
3. Loss of iron.

He showed that in some cases the acidity in the gastric juice gradually diminished as pregnancy proceeded and in the cases in which the acidity was lessened there usually was more loss of hemoglobin. The diet of these patients is apparently a factor. A good diet consists of meat and vegetables. In patients in whom the diet was not especially rich in meat and vegetables there was more anemia. It is interesting to note that in these cases pallor is not a pronounced symptom. Under the microscope the red blood cells are usually smaller than normal, have some change in shape but little change in size and there is distinct achromia. He showed charts to emphasize the fact that, despite the anemia in the mother, practically all the babies are born with the same amount of hemoglobin and are not anemic at birth.

The treatment of this condition consists of iron in adequate amounts. The type of iron administered is not important but it is essential to see that enough is absorbed to accomplish the results. Ferrous salts are more effective than ferric salts and therefore it is important to see that the iron is not oxidized. Most pharmaceutical houses arrange

their preparations so that oxidation does not take place

Occasionally an anemia is spoken of as macrocytic anemia, which is similar to pernicious anemia and occurs in pregnancy but this is very rare. This anemia is apparently due to a lack of an intrinsic factor in the gastric juice which is essential to prevent primary anemia or a lack of the liver factor in the diet, or an inability to absorb this factor. In the few cases of macrocytic anemia which have been observed in Boston, it is felt that the cause is due to a lowering of the intrinsic factor in the gastric juice rather than to a disturbance in absorption or a lack of the liver element in the diet. Some comparison has been made with cases in India in which a lack of the liver element in the diet is the important factor. Apparently in certain cases the intrinsic factor in the gastric juice, which is important in anemia, may temporarily diminish in pregnancy. This type of anemia should be treated with liver extract and usually the liver extract can be stopped after the blood has returned to normal. Transfusions are not indicated unless the anemia has reached such a severe grade that it becomes a temporary emergency.

Another interesting observation was the fact that babies of untreated anemic mothers tended to be anemic at the end of a year, while babies of mothers who are not anemic and babies of mothers who were anemic but were treated did not show anemia at the end of a year.

ALPHA OMEGA ALPHA LECTURE

The first Alpha Omega Alpha Lecture of the current academic year was delivered at the Harvard Medical School December 12, 1935, by Dr. Warfield T. Longcope, Professor of Medicine at the Johns Hopkins University Medical School, who spoke on "Studies in the Natural History of Bright's Disease."

Bright's disease must be considered as a general systemic disease, in which the renal lesions are but a part of the many manifestations. The renal involvement may be considered analogous to the involvement of the heart in such diseases as rheumatic fever and syphilis. Acute hemorrhagic nephritis was selected for study with the hope of clarifying its etiology and pathogenesis.

At least 90 per cent of the cases of acute hemorrhagic nephritis follow infections with hemolytic streptococci, and recent work has shown that the majority of these cases occur after infections caused by the beta, or minute form of the organism. The mode of action of these bacteria in producing the disease has been investigated by many workers. Acute glomerular reactions have been produced in animals by injections of the toxins of hemolytic streptococci, and by severe peritoneal infections with the same organism. Pappenheimer sensitized animals to streptococcal proteins, and subsequently injected the dead bacteria into the renal artery, with the production of acute glomerular

lesions, which appeared identical microscopically with those of acute glomerular nephritis. Dr. Longcope obtained similar results with injections of *Streptococcus viridans*, the lesions produced being more diffuse and extensive than those obtained from injections of *Streptococcus hemolyticus*. Only certain strains of each group were effective, however.

Of the 125 cases investigated by Dr. Longcope, a characteristic prodromal period followed the acute infection before the onset of the nephritis. This period varied from three to twenty-eight days, and eighty per cent of the cases appeared between the seventh and sixteenth days.

Although acute hemorrhagic nephritis resembles rheumatic fever in appearing after infection with beta hemolytic streptococcus, there are several important differences between the pathogenesis and epidemiology of the two diseases. The primary infection in acute glomerular nephritis unlike rheumatic fever is not always confined to the respiratory tract, since cases have been observed following impetigo, erysipelas, and wound infections. The variation between the climatic distributions of the two diseases is quite striking, for whereas the incidence of rheumatic fever falls progressively from the cold climates of the north to the semitropical climates of the south, the incidence of acute glomerular nephritis is practically identical in the two areas. Rheumatic fever is prone to undergo exacerbations, while acute glomerular nephritis once cured does not recur.

Careful study of fatal cases has shown that the majority of fatalities are characterized by an insidious onset following subacute recurring infections (e.g., infected sinuses) of streptococcal etiology. Such cases may show edema and albuminuria, and gradually develop marked and persistent elevation of the blood pressure. They proceed with a subacute course, and recurrence of edema, fever, and hematuria with each flare-up of infection.

These findings have led Dr. Longcope to consider that there are two types of hemorrhagic glomerular nephritis, each with a characteristic clinical course and termination. The first type is characterized by an abrupt onset, an acute course, and usually terminates with healing. The second has an insidious onset, subacute course with remissions and exacerbations, and frequently terminates fatally. There is some question as to whether the latter type is due to streptococcal infection. It is true that pneumococcal infections are able to produce this type of disease.

Patients with the acute form show a high titer of antistreptolysins in the blood serum following acute infections. Patients with the subacute, progressive form of the disease have a persistent low titer. The former group shows a good skin reaction to filtrates or proteins of the bacteria, in contrast to the latter group, which only rarely shows such a reaction.

Thus the two forms may be considered as infectious diseases, in which the reaction of the individ-

nal to the infection is different. The antitoxin reaction power of the patient of the first class is highly active but is depressed or absent in the subacute group.

Treatment of acute hemorrhagic nephritis must be based on the fundamental principles of treatment of any acute infection involving a vital organ. Special attention must be paid to eradicating the seat of focal infection.

SOUTH END MEDICAL CLUB

The next regular meeting of the South End Medical Club will be held at the office of the Boston Tuberculosis Association, 554 Columbus Avenue, Boston, on Tuesday, January 21, at 12 noon. The speaker will be James W. Manary, M.D., Superintendent and Medical Director of the Boston City Hospital. His subject will be "The Growth of Dispensary Service at the Boston City Hospital." All physicians are cordially invited to attend this meeting. The usual luncheon will be served.

THE AMERICAN COLLEGE OF PHYSICIANS

The Twentieth Annual Session of the American College of Physicians will be held in Detroit with headquarters at the Book-Cadillac Hotel, March 2-6, 1936.

Dr. James Alex. Miller of New York City is President of the College and has arranged a program of general scientific sessions of great interest to those engaged in the practice of Internal Medicine and associated specialties. Dr. Charles G. Jennings of Detroit is the General Chairman of the Session and is in charge of the program of clinics and demonstrations in the hospital, medical schools and other Detroit institutions. Dr. James D. Bruce, Vice-President in Charge of University Relations, University of Michigan, is Vice-Chairman of the Committee on Arrangements and has in charge the preparation of an all-day program to be conducted at the University of Michigan on Wednesday, March 4. Dr. Walter B. Cannon, Professor of Physiology at Harvard University Medical School, will deliver the annual Convocation Oration on "The Role of Emotion in Disease." Dr. Miller's presidential address will be on "The Changing Order in Medicine." About fifty eminent authorities will present papers at the general scientific sessions, while clinics and demonstrations will be conducted at the Harper Receiving Ford, Grace Herman Klefer and Children's Hospitals of Detroit.

NEW ENGLAND PHYSICAL THERAPY SOCIETY

The regular meeting of the New England Physical Therapy Society will be held at the Hotel Kenmore, Boston, on Wednesday evening, January 15, 1936, at 8 P.M.

PROGRAM

Hypersensitive Rhinitis and Its Treatment (Illustrated). The Modern Treatment of the Common Cold. George B. Rice, M.D., Boston.

The discussion will be led by Leighton F. Johnson, M.D., Boston.

The Progress Committee will submit a report on evaluation and progress in the field of short wave therapy by DeWitt G. Wilcox, M.D. of Newton and William D. McFee, M.D., of Boston.

The Council will meet at six.
Members and guests will meet at dinner in the main dining room of the Hotel Kenmore at six thirty.

All members of the medical profession are cordially invited to attend.

WILLIAM D. McFEE, M.D., Secretary

THE ARLINGTON DOCTORS CLUB

The regular meeting of the Arlington Doctors Club will be held at the Ring Sanatorium on Tuesday, January 14, at 8:30 P.M.

The Belmont Doctors Club has been invited to attend.

The speaker will be Dr. Conrad Wesselhoef, Assistant Professor of Communicable Diseases, Harvard Medical School and Medical Director of the Haynes Memorial Hospital.

His subject will be "Problems in Scarlet Fever." All physicians are invited to attend.

FRANK H. GERRY, President

SIMON M. SIMON, Secretary

HARVARD MEDICAL SOCIETY

The next meeting of the Harvard Medical Society will be held in the Peter Bent Brigham Hospital Amphitheatre (Shattuck Street Entrance) Tuesday evening, January 14, at 8:15 P.M.

PROGRAM

Presentation of Cases.
The Physiology of the Elephant. By Dr. Francis G. Benedict.

Medical students and physicians are cordially invited to attend.

MARSHALL V. FULTON, M.D., Secretary

SOCIETY MEETINGS CONGRESSES AND CONFERENCES

CALENDAR OF BOSTON DISTRICT FOR THE WEEK
BEGINNING MONDAY, JANUARY 13, 1936

Tuesday, January 14—

9:10 A.M. Boston Dispensary, 5 Bennet Street, Boston. Cases from Blood Clinic. Dr. Isadore Olet.

2:30 P.M. Pediatric Ward Visit, Massachusetts Eye and Ear Infirmary.

7:45 P.M. Gardner Auditorium, State House, Boston. Adults in Difficulty. A. Warren Stearns, M.D.

*8:15 P.M. Harvard Medical Society, Peter Bent Brigham Hospital Amphitheatre (Shattuck Street Entrance).

8:30 P.M. The Arlington Doctors Club at the Ring Sanatorium.

Wednesday, January 15—

8:10 A.M. Boston Dispensary, Bennet Street, Boston. Modification of History Taking and Physical Examination Methods in Pediatrics. Dr. Francis McDonald.

11 A.M. Clinico-Pathological Conference, Children's Hospital.

8 P.M. New England Physical Therapy Society, Hotel Kenmore, Boston.

Thursday, January 16—

- *8 30-9 30 A M Clinic, Surgical and Orthopedic Staffs of Children's Hospital, at the Children's Hospital
- *9-10 A.M. Boston Dispensary, 25 Bennet Street, Boston Social Service Case Presentation. Miss Edith Canterbury
- *2 30 P M Medical Clinic at the Peter Bent Brigham Hospital

Friday, January 17—

- *9-10 A.M. Boston Dispensary 25 Bonnet Street, Boston The Diagnosis and Management of Biliary Tract Disease Frank Lahey, M D
- 12 M Massachusetts General Hospital, Clinical Meeting of the Staff of the Children's Medical Service Ether Dome

Saturday, January 18—

- *9-10 A M Boston Dispensary 25 Bennet Street, Boston Presentation of Ward Cases Dr H C Gordonier
- *10-12 Staff rounds at the Peter Bent Brigham Hospital

Sunday, January 19—

- 4 P M Free Public Lecture, Harvard Medical School, Building D, Longwood Avenue The Prevention of Infectious Diseases Dr H C Stuart.

*Open to the medical profession

NUMBER 3

PRIMARY CARCINOMA OF THE LUNG EARLY DIAGNOSIS AND TREATMENT BY PNEUMONECTOMY*

BY RICHARD H. OVERHOLT, M.D.†

THE surgical treatment of malignant disease has been based upon the complete extirpation of cancer bearing tissue or of a cancerous organ before the onset of metastasis. The success of such treatment has been dependent upon early diagnosis and upon accessibility of the organ for safe resection. The presence of a malignant process in a vital organ has naturally been considered hopeless so far as surgical treatment is concerned. It has now been demonstrated however, that one lobe of a lung or the entire lung on one side can be successfully removed. It has also been shown that the procedure does not limit the patient's ability to enjoy the ordinary activities of life.

This paper relates experiences in the surgical treatment of carcinoma of the lung, compares the status of the patients operated on with that of untreated patients, and discusses diagnostic methods which should help to bring the patient under treatment at a time when the growth is confined within the lung.

Hitherto many of the published data on carcinoma of the lung have come from analysis of autopsy material. The concept derived from such sources has naturally focused attention on the late stages of the disease. The recent advances in the surgical treatment of primary carcinoma of the lung therefore demand that the general medical profession be more concerned with early symptoms and differential diagnosis. Patients should receive the benefit of treatment while the lesion is still local in its extent. Fortunately, several facts regarding primary lung carcinoma are now known which will make early diagnosis possible in a fair proportion of cases. 1. A warning symptom, a persistent cough appears early. 2. A large majority of the growths originate in a stem bronchus and therefore can be actually visualized (with the aid of the bronchoscope). 3. The stem bronchus lesion is limited by cartilaginous rings and apparently grows slowly over a period of months until the infiltrating process breaks through these bounds. Awareness of the possibility of the presence of such a lesion, and the application of methods now available for early detection, should greatly

increase the percentage of operable cases. A new ray of hope for a group of cases previously considered always to have a fatal outcome has appeared on the medical horizon.

That surgery promises some help for patients doomed on account of primary malignancy of the lung is more welcome since it is generally admitted that irradiation in any form fails to cure and frequently does not even influence, for the better, the progress of the disease. So far as I know, there has not been reported a five-year cure of a proved primary carcinoma of the lung by deep roentgen ray therapy, or by direct bronchoscopic radium implantation. Tittle and Womack¹ in a report of eighteen cases said, "The use of radiation in the form of either local application of radon seeds, or as x ray therapy has been unsatisfactory." Edwards², in summarizing his experiences with the direct implantation of radon said, "Nevertheless, it can not be denied that the majority of thirty two patients submitted to this treatment have died of their growths." At the time of Edwards' report, one patient was living with an apparent disappearance of the growth three years after treatment and one patient four years after thoracotomy and direct radon implantation.

From our knowledge at the present time of the action of radiation on primary tumors of the lung it would seem unlikely that much reliance can be placed upon this form of treatment. In the first place, the most common type of primary malignant disease in the lung is the epidermoid form, which is notably radio-resistant. Secondly, the associated breakdown of pulmonary tissue with emphysema in the region of the growth leaves the patient with a serious condition in the chest whether the malignant lesion is actively growing or not. Radiation may aggravate this destructive inflammatory process thereby leaving the patient in a more uncomfortable state than ever.

Bronchoscopic removal of a very small bronchial neoplasm must always be considered as a possible form of treatment. Kernan³ has reported at least temporary improvement in a limited number of cases followed two and three years. Jackson and Konzelmann⁴ however, in a series of twenty nine cases, found no lesions small enough to treat in this way. All of the cases in their group who had been followed had

died of the disease, except the three most recent ones

SUCCESS IN THE RADICAL OPERATION

Efforts on the part of thoracic surgeons to cure primary malignant disease of the lung have been stimulated by successful experiences with lobectomy for bronchiectasis. There have been a limited number of attempts in the past few years to treat pulmonary malignant disease by resecting a single lobe. Operative successes have been reported by Sauerbruch⁶, Churchill⁶, Edwards² and Eggers⁷. A recent account has been given by Allen⁸ of the survival of a patient four years after lobectomy for carcinoma of the right lower pulmonary lobe. In Allen's cases, however, bronchoscopy two and one-half years after operation revealed a malignant growth in the stump of the right lower bronchus indicating that the resection had not been high enough in the hilum. In 1932 the author⁹ had a similar experience with lobectomy for carcinoma of the right lower lobe. Not all of the growth was removed and the patient died of the disease ten months later. In the large majority of cases when the lesion has originated in one of the major bronchi, it is impossible to resect the corresponding lobe and be sure of removing all of the growth. Thoracic surgeons now feel that in most cases of malignant disease the entire lung should be removed and the bronchus divided as high as possible.

Within the past four years, it has been demonstrated that the resection of one entire lung (pneumonec-tomy) can be done with survival of the patient and without subsequent disabil-

the following year had four additional successful resections of the lung, two for cancer and two for pulmonary suppuration. See table 1. Other successes with this operation for carcinoma of the lung (Archibald, Churchill, Haight, and Flick) have been noted in a recent article by Alexander¹⁰.

The postoperative period of observation is too limited in all of the reported successful cases to draw final conclusions. Two carcinoma cases operated on by the author have lived twenty and fourteen months respectively, have remained free of symptoms and show no evidence of recurrence. See figure 1. Their present status

FIGURE 1. Photograph of two patients who are now living and well 20 months and 14 months respectively following pneumonec-tomy for primary carcinoma of the lung. The patient on the left had the right lung removed on November 2, 1933 and later had an eight rib thoracoplasty to obliterate the space. The patient on the right had the left lung removed on May 2, 1934. A thoracoplasty was not required. Both patients do their own housework and both show no evidence of metastasis.

is, therefore, far better than that of the other nineteen cases seen during the past three years who either were not treated surgically or were found upon exploration to have metastatic growths. Of these nineteen patients, fifteen are dead, a follow-up report has not been obtained from one, and three patients are still living, all of whom have been studied within the past five months. Of those that died, the average survival was sixteen months after the onset of symptoms and 35 months after the diagnosis was established. Two of the surgically treated cases, therefore, have exceeded their estimated expectancy by thirteen and seven months respectively. The third successful pneumonec-tomy for carcinoma has been done recently (April, 1935). The study of the cases in our series would suggest that surgical treatment gives the greatest prospect of cure.

The success of our attempts to salvage such patients will depend upon two factors: first, early diagnosis and early operation before the lesion has spread beyond the lung, and secondly, careful management before, during, and after operation to minimize operative morbidity and mortality.

ity. The successful removal of the left lung for bronchiectasis performed in stages has been reported by Nissen¹⁰, Haight¹¹, and Windsberg¹². Graham and Singer¹³ in 1933 removed the left lung for carcinoma. In the same year Rienschhoff¹⁴ reported two successful left pneumonec-tomies. Also in 1933 the author¹⁵ removed the entire right lung for carcinoma and in

PATHOLOGY

In order to correlate symptoms establish a diagnosis and determine operability in any given case of malignant disease, it is well to consider first the histology and site of origin of the lesion. Although there has been some confusion about the classification of primary lung tumors, it is now generally conceded that the great majority of primary lung tumors arise from cells in the bronchial epithelium or from the bronchial mucous glands. Origin in the cells of the pulmonary alveoli possibly never occurs or is so rare that it can well be dismissed. Various classifications of primary lung carcinoma have been given, based on histology, gross appearance, and location. From the histologic standpoint, the epidermoid form is most frequently encountered. In twenty of our cases, the following pathological diagnoses were made by Dr. Shuclds Warren:

	No cases	Metastatic growths found by x ray exploratory thoracotomy or autopsy	No metastatic process found at operation or autopsy
Epidermoid Carcinoma	11	9	3
Carcinoma Simplex	4	2	2
Adenocarcinoma	2	1	1
Carcinoma—unclassified	3	1	1

This proportion of histological types corresponds closely to that reported in other groups of cases. The location of the lesion in the lung, however, apparently influences the clinical picture more than does the histological structure of the growth. A tumor near the hilum and growing within the lumen of a major bronchus produces an entirely different gross appearance and gives an entirely different x ray shadow than does a lesion growing in the periphery of the lung.

Most writers, therefore, have created two major groups, one for growths arising in the major bronchi and near the hilum (bronchial form) and another arising in the periphery of the lung (pneumonic form). It is impossible to fit the various histological groups into the two major forms of lung cancer which are based on location. It is the opinion of Geschickter and Denison¹⁷, however, that the hilar lesions are usually carcinomata of the epidermoid form where as the peripheral lesions are usually adenocarcinomata. In our series, nineteen were of the hilar type and four were peripheral. There were two adenocarcinomata in all, one being located peripherally and the other centrally.

We have been unable to formulate any rule

that would correlate the frequency of metastasis with the various histological forms. In one patient, a large peripheral adenocarcinoma had directly infiltrated the chest wall but showed no mediastinal or lymphatic involvement. Most of the epidermoid tumors at the time of investigation showed extension into the mediastinum. However, in two cases the bronchoscopic biopsy revealed a rather highly ma-

lignant lesion, carcinoma simplex grade III yet no metastatic extensions were found at operation, and pneumonectomy was successfully performed. In one case, the lesion was known to have been present at least two years. There were two additional cases in the series in which the lesion was a carcinoma simplex at the time of investigation, these remaining two showed metastatic growths. There were three definitely malignant lesions of epidermoid origin which Dr. Warren was unable to classify. Only one of these showed metastasis. Pneumonectomy was done in the other two cases, and one of these was successful.

At the present time, it is impossible to predict which histological group will ultimately lend itself best to surgical treatment. Until more is known concerning the growth and spread of these tumors, all should be considered operable unless a mediastinal extension or a definite metastatic lesion can be demonstrated.

LOCATION OF THE GROWTH

The location of the growth and its relation to the stem bronchus has more to do with the clinical picture which the tumor produces than does its histologic structure. As was stated above, most writers have designated two distinct clinical groups of primary lung cancer based upon the location of the growth. All agree that the majority of the tumors arise in

one of the major bronchi near the hilum Rabin and Neuho¹⁶ in their series of cases found that seventy-five per cent took origin in a main or branch bronchus Tuttle and Womack¹ found fifty-two per cent of the lesions of the bronchial or hilar type In those cases reported by Geschickter and Denison¹⁷ sixty-five per cent were hilar in position In a series of twenty-three cases studied in The Lahey Clinic all but four had their origin in a stem bronchus

That the large majority of the primary malignant lesions of the lung are in this location is extremely important from the standpoint of detection, biopsy diagnosis and surgical treatment

BRONCHIAL FORM

A concept of the early clinical picture and the progressive development of symptoms in primary carcinoma of the lung can best be presented by considering the two forms separately All of the important early symptoms of a stem bronchus cancer are due to mechanical disturbances produced by virtue of the position of the growth in the lumen of one of the major bronchi In figure 2 are shown two dif-

BRONCHIAL FORM

EARLY LESION
BRONCHUS OPEN

LATER LESION
BRONCHUS OCCLUDED

FIGURE 2 Diagram illustrating bronchial form of primary carcinoma of the lung Seventy to eighty per cent of primary lung cancers originate in the stem bronchus The lesion rarely casts a shadow in the x-ray Its presence is not suspected until the lumen of a bronchus is occluded Then the shadow of atelectasis appears The bronchial type of lesion can be seen early by the use of the bronchoscope.

ferent stages in the growth of a tumor in a stem bronchus The first drawing shows a small lesion in one of the major bronchi, too small to occlude its lumen Such a lesion would produce a chronic and persistent cough Erosion of the surface would give rise to hemoptysis An x-ray examination at this time would be negative since the tumor itself could not be

visualized and since there is no interference with the aeration of the corresponding lobe A diagnosis could be made only by direct inspection of the bronchial tree with the bronchoscope As the growth enlarges and partially closes the lumen of the bronchus, the patient may become conscious of a wheezing sensation in the chest A mistaken diagnosis of asthma is not uncommonly made

When the growth completely blocks the lumen of the bronchus, other symptoms and signs are added to the meager tell-tale evidences of the nonobstructing lesion The roentgenogram shows atelectasis of the affected lobe, usually a homogeneous shadow, triangular in shape, with the apex reaching the hilum (figure 2B) The growth itself may attain a size large enough to cast a shadow, thus giving direct x-ray evidence of the tumor In figure 3, the

FIGURE 3 Roentgenogram of the chest of a patient showing both the shadow of the tumor near the hilum and also a triangular area of density indicative of atelectasis of the right lower lobe Both the direct evidence (tumor shadow) and presumptive evidence (atelectasis) were shown by this x-ray Right pneumonectomy was successfully performed on November 2, 1933 See figure 1

roentgenogram of such a case is reproduced Both the presumptive x-ray evidence (atelectasis) and the direct x-ray evidence (tumor mass) are shown In figure 4, the mass itself cannot be seen, but atelectasis of the lower lobe is shown together with obstructive emphysema of the upper lobe From the x-ray appearance alone, the growth was located at the bifurcation of the secondary bronchi completely obstructing the lower, partially obstructing the upper bronchus In figure 5 is shown the roentgenogram of a lesion in the left upper main bronchus

The growth itself is not seen but the associated atelectasis is typical.

After the growth has obstructed the bronchus,

FIGURE 4 Roentgenogram of a patient who had a primary carcinoma at the bifurcation of the left main bronchus. The tumor itself does not cast a shadow. The left lower lobe bronchus was completely occluded so that the typical triangular shadow of obstructive atelectasis is present. The upper lobe bronchus was partially occluded, a valve-like action resulting in an emphysema of the upper lobe took place. In this case the x-ray yielded presumptive evidence only of a tumor of the bronchus. A left pneumonectomy was successfully performed on May 1934. See Figure 1.

FIGURE 5 Roentgenogram of a patient with a primary carcinoma of the left upper lobe bronchus. The tumor itself did not cast a shadow. The area of density in the upper portion of the left chest with slight displacement of the mediastinum toward the left side is typical of atelectasis of the upper lobe (presumptive evidence). A left pneumonectomy was successfully performed on April 8, 1935.

the effects of retained secretions and infection become superimposed. The cough becomes productive and the sputum may be foul. Recurrent elevations of temperature are frequently noted

in the histories of such patients and not a few have been told they had pneumonia or even more frequently tuberculosis. Later such symptoms as pain in the chest, dyspnea, and weakness develop. Symptoms due to a late stage of the disease with infiltration of the mediastinum have no place in the construction of a practical concept of this disease.

In a review of the earliest symptoms in nineteen cases of bronchiogenic carcinoma, cough was reported by all to be an early and persistent symptom. Twelve patients complained of weakness and eight of hemoptysis. The duration of symptoms extended over a period of four to twenty-four months. Throughout this entire time persistent cough was the symptom that urged them to go from doctor to doctor searching for relief. Practically every patient had previously been considered to have either tuberculosis, pulmonary abscess, or unresolved pneumonia. The roentgenographic examination in the early stages may be confusing in that the lesion, itself, may not cast a shadow or the shadow may be difficult of interpretation because of its close proximity to the hilar shadow. When an abnormal shadow is seen in the x-ray, it is due to the secondary effect of the tumor and not to the tumor itself. These secondary effects show up as those of atelectasis of the corresponding lobe. Sputum tests help to rule out tuberculosis and may help in differentiating lung abscess. Reliance must be placed upon bronchoscopic examination. In our series, fifteen of the cases with stem bronchus lesions were examined bronchoscopically and a tumor visualized in fourteen and a positive biopsy obtained in all of the fourteen. From our study of the bronchial type of carcinoma, it has been concluded that no group of symptoms can be outlined which will truly represent the disease. All patients of middle age or past middle age who develop a chronic and persistent unexplained cough should be studied bronchoscopically.

PNEUMONIC FORM

A tumor originating in the periphery of the lung differs greatly from the stem bronchus lesion in its clinical picture. The size that it attains before producing symptoms varies considerably because obstruction of a major bronchus is not a factor. The position of the lesion, its relation to the visceral pleura, the rapidity of central necrosis and secondary infection all contribute to the development of symptoms. A correlation of tumor growth and symptoms has been diagrammatically shown in figure 6. A peripheral growth would obviously produce an area of density in the roentgenogram early in its development. The lesion casts a homogeneous shadow and is fairly well circumscribed. Cough is one of the early symptoms and may be the only symptom. Hemoptysis at this time is not so likely as in the stem bronchus lesion.

As the disease progresses, the x-ray shadow increases in size and may show areas of cavitation. Later, superimposed infection and tissue necrosis result in appearances not unlike that seen in pulmonary abscess or suppuration. Weakness, loss of weight, and other evidences of sepsis appear. Cases in our series showing this type of lesion have been previously diagnosed either tuberculosis or lung abscess. In figures 6 and 7 are shown the roentgenograms

is reported in detail elsewhere¹⁵. In two of our malignant cases, a thoracotomy and drainage of the area was carried out because the history,

FIGURE 6 Diagram illustrating the stages of development of a pneumonic or peripheral form of primary carcinoma of the lung. In the early stage cough may be the only symptom. The x-ray shadow may resemble lung abscess or tuberculosis. As the lesion breaks down and as the effects of suppuration are superimposed a different clinical picture is presented. This form of primary malignancy of the lung is difficult to diagnose as bronchoscopy fails to visualize the tumor. Fortunately, this type is less frequent than the stem bronchus lesions.

of a patient who had a peripheral lesion which later proved to be an adenocarcinoma. Bronchography revealed no connection between the tumor and the major bronchi. The lesion had infiltrated the chest wall. An aspiration biopsy was done but with negative results. Bronchoscopy was likewise negative. A presumptive diagnosis of neoplasm was made from the history and from the x-ray appearance. An exploratory thoracotomy was then carried out and a large peripheral lung tumor found and a pneumonectomy performed. This case

FIGURE 7 Roentgenogram of a patient who had a pneumonic form (adenocarcinoma) of the right lung. Bronchoscopy failed to visualize the tumor. The diagnosis was made by exploratory thoracotomy.

FIGURE 8 Roentgenogram of the same patient as in figure 7. Lipiodol injection revealed no connection between the tumor mass and the major bronchi. This illustrates an additional aid in the diagnosis of such lesions.

physical signs, and x-ray, and sputum examinations all supported a diagnosis of pulmonary abscess. Edwards² reports that ten per cent

of pulmonary abscesses, so diagnosed, are primary neoplastic lesions which have broken down.

In the pneumonic forms, bronchoscopic examinations failed to be of positive assistance in establishing the diagnosis. In all four cases no abnormal condition of the tracheobronchial tree was visualized bronchoscopically. The procedure was valuable, however, in eliminating other conditions that might cause such symptoms. The most important points in the diagnosis of the pneumonic form are symptoms such as cough, weakness, hemoptysis, and chest pain combined with the x ray picture of a progressive, nonfibrosing lesion. It is frequently possible to secure x ray films taken at an earlier date with which to make a comparison. An inflammatory process in one of the lobes or a chronic interlobar empyema may be confusing.

The question then arises: Are there any other aids in the diagnosis of the pneumonic form of cancer? We have injected lipiodol in all suspected cases when bronchoscopy failed to help. Visualization by x ray of the tracheobronchial tree may aid in ruling out other conditions which give rise to cough, expectoration and hemoptysis. An examination of the sputum is valuable in ruling out tuberculosis or a suppurative process. The induction of a partial pneumothorax with subsequent x ray examination may help to establish the relationship of the lesion to the chest wall, pleura, and great fissures. There is always the possibility of getting tissue for biopsy by aspiration of peripheral lesions when an adherent pleura is present. We have attempted to obtain material for histologic study by this method without success. The procedure may not be without danger. In the event, therefore, of not being able to secure a direct specimen for biopsy either bronchoscopically or by aspiration, we feel that thoracic exploration is indicated. If we wait for extension of the growth to take place, the chance of cure by pneumonectomy is lost.

DETERMINATION OF OPERABILITY

It is our feeling that all cases with proved or suspected primary malignant disease of the lung should be subjected to exploratory thoracotomy provided that

- 1 The lesion is presumably still limited in its extent to one lung. Metastatic cervical glands should be looked for. The skull, long bones, ribs and spine should be examined roentgenoscopically for metastatic lesions. If pneumothorax can be effected a direct inspection of the pleural cavity with the thoracoscope may be of great value.
- 2 The general condition of the patient is fair. All of the patients who have survived pneumonectomy were in the grade III or IV group of operable risk. All but two

were febrile at the time of operation. If their symptoms are due solely to the disease in the affected lung, removal of this organ immediately relieves the patient of absorption from this area. Therefore, the extent of the tumor or the associated pathologic conditions within the one lung should not of itself contraindicate operation. Whenever possible patients are prepared for thoracic exploration by the preliminary induction of pneumothorax. As a rule it has taken five to seven days to achieve maximal collapse. If adhesions of the pleura prevent more than thirty per cent collapse the operation is undertaken without delay. Should more than thirty per cent collapse be obtained, pneumothorax is maintained for seven to ten days more. This length of time seems to be adequate to test the function of the remaining lung and to adjust the circulatory and respiratory apparatus to atmospheric pressure on the affected side.

Operative technique will not be discussed in detail in this paper.

Either an anterolateral or posterolateral approach is used depending upon the extent and location of adhesions and upon the position of the tumor. The mediastinum is inspected and palpated. If there is an obvious infiltration of this region or if mediastinal glands are enlarged and show metastatic involvement on frozen section, the operation is concluded and the thoracic wound closed. If no evidence of metastasis is discovered pneumonectomy is carried out. Problems in the surgical management of the pneumonectomy patient have been discussed in another paper devoted to this aspect of the subject.¹¹

THE CHALLENGE

It has been demonstrated that the resection of the entire lung on one side is technically possible and that the consequence of such a procedure is not incapacitating. It has also been pointed out that a diagnosis of primary malignancy of the lung can be made before the patient reaches the autopsy table. An analysis of the cases in our series and the experiences of others show that the large majority of all primary carcinomas of the lung originate in a major division of the right or left main bronchus. Therefore the majority of these lesions can be actually seen early in their development and a biopsy obtained by means of the bronchoscope. Cough and hemoptysis occurred in a large proportion of all cases early in the course of the disease. Fortunately we have therefore an early warning symptom. We are obligated to heed this warning sign and if no adequate explanation is forthcoming after sputum and x ray examinations the patient should be subjected to bronchoscopy.

It should also be emphasized that in the early stages of stem bronchus lesions, the lesion itself, does not cast a shadow on the x-ray film. The x-ray diagnosis depends upon secondary evidences of growth, namely, atelectasis.

An opinion in regard to exploratory thoracotomy has also been expressed, namely, in all cases of proved malignancy, explore if metastasis cannot be demonstrated. In peripheral lesions, exploration is justified without a positive biopsy diagnosis. The thoracic exploration may be the only possible way to settle the diagnosis at a time when the growth is in the operable stage.

SUMMARY

- 1 A study of twenty-three cases of primary carcinoma of the lung has been made.
- 2 The bronchial and pneumonic forms are differentiated, and diagrams illustrative of these two types of pulmonary malignancy are shown.
- 3 Emphasis is placed upon early symptoms. A chronic unexplained cough is the most frequent early symptom. Expectoration, hemoptysis, and wheezing may be present fairly early.
- 4 The value of diagnostic aids, such as x-ray, bronchoscopy, lipiodol visualization, pneumothorax, and intrapleural thoracoscopy has been pointed out.
- 5 The ineffectiveness of any form of radiation has been discussed.

- 6 The possible cure of primary carcinoma of the lung by resection of an entire lung has been considered.
- 7 Five successful pneumonectomies are reported—three for malignant and two for suppurative disease.

VENEREAL DISEASE INFORMATION

It is desired to invite your attention to *Venereal Disease Information*, a monthly publication prepared by the U S Public Health Service for the medical profession throughout the United States. The purpose of this publication is to provide in condensed form a monthly summary of the scientific developments in the diagnosis, treatment, and control of syphilis and gonorrhea. More than three hundred and fifty American and foreign journals are reviewed for this work and abstracts are made of articles describing clinical, laboratory, and pathologic work in the field of venereal disease. The most important literature on every phase of the subject is presented in the form of brief abstracts that are easily read. An index for the year is published with the December issue.

Thousands of physicians have found this publication useful in enabling them to keep abreast with developments in venereal disease work. During the coming year it is planned to publish several original articles by outstanding authorities in this country in the field of syphilis and gonorrhea. The series of articles on the treatment of syphilis by the cooperative clinical group has not yet been completed. A number of interesting papers, among which will be

two—one on cardiovascular syphilis and one on syphilis of the nervous system, will be published in the near future.

The cost of this publication is only fifty cents per annum, payable in advance to the Superintendent of Documents, Government Printing Office, Washington, D C. It is desired to remind the reader that this nominal charge represents only a very small portion of the total expense of preparation, the journal being a contribution of the Public Health Service in its program with State and local health departments directed against the venereal diseases.

A sample copy of *Venereal Disease Information* will be forwarded to you upon request. To receive this copy address the Surgeon General, U S Public Health Service, Washington, D C. Do not send stamps.

NEW ENGLAND SURGICAL SOCIETY

DeQUERVAIN'S DISEASE*

Stenosing Tendovaginitis At The Radial Styloid

DR DANIEL C PATTERSON, M.D.†

THIS condition was first described by DeQuervain in 1895 as a relative narrowing of the compartment of the tendon sheath lying on the styloid process of the radius which transmits the extensor brevis pollicis and the abductor longus pollicis. Kocher gave it the name of stenosing fibrous tendovaginitis. Many articles dealing with the disease have appeared in foreign journals, but I have found only three papers by American authors.

In 1927 Dr H. C. Stein reported on five cases treated at the Hospital for Joint Diseases in New York. In 1928 Dr C. C. Schneider of Milwaukee reported fifteen cases that he had treated, and in 1930 Dr Harry Finkelstein reviewed the literature, and reported twenty-four cases that had been treated at the Hospital for Joint Diseases in New York in a two year period. He also gave the results of microscopic studies and demonstrated that the disease could be produced experimentally in rabbits.

I believe that the disease is not generally recognized, and that quite a number of cases are under treatment for sprain, arthritis, neuritis, osteitis, periostitis or tenosynovitis.

The tendons of the abductor longus pollicis and the extensor brevis pollicis pass through a groove in the outer aspect of the styloid process of the radius, and are contained in a separate compartment of the annular ligament. They are surrounded by a tendon sheath that extends about an inch above and below the carpal ligament. This sheath is filled with synovial fluid to facilitate the pulley-like action of the tendons.

The essential pathological change in DeQuervain's disease is a thickening of the tendon sheath, and the overlying carpal ligament. This causes a marked narrowing of the channel through which the tendons pass, the tendons themselves rarely show any change in structure.

Finkelstein recorded his microscopical findings as follows: "In mild cases the synovial membrane is thickened except at the point of constriction where it is thin or absent. The loose connective tissue layer is considerably thickened and vascularized. The ligamentous layer is slightly thickened and not vascularized. Only rarely is there a line of demarcation between

the loose connective tissue layer, and the ligamentous layer. In severe cases the synovial layer is completely destroyed, the loose connective tissue layer is compressed and thinned out, while the ligamentous layer is markedly thickened and undergoes hyaline and cartilaginous transformation. There is also marked thickening of the walls of blood vessels, and cellular infiltration of the tissues, numerous lymphocytes being present. Between these two types are many gradations." All of our sections have shown similar changes.

Similar changes have been observed where other tendons have been involved, namely, the extensor longus pollicis, and the extensor carpi ulnaris, but only a very few such cases have been encountered. Several instances of the disease in association with snapping thumb have also been reported. In these cases a small nodule was found on the tendon and produced the snapping when it slid under the thickened ligament.

The etiological factor is undoubtedly trauma and this in most cases of a chronic nature. In our cases the patients were all engaged in occupations that required pressure by the thumb while it was in a partially abducted position and the hand in ulnar abduction, such as work on a grinding or buffing machine. In one case the patient, a woman, was employed putting tight fitting rubber rings over a piece of pipe. To do this she would press firmly on the ring with both thumbs. One day in order to complete a rush order she performed this act five hundred times. That night she had severe pain in both thumbs. This is the only case I have seen where the condition could be said to have an acute onset. It was also the only bilateral case in our series.

Some cases have been reported to have followed a severe blow over the styloid process but we have not seen any giving such a history. One or two patients thought that their trouble started after a fall.

The cause of the thickening in the tendon sheath and carpal ligament is principally mechanical. Eschle thinks it is due to friction of the tendons in their narrow compartment that overexertion causes the increased friction, and the tendon sheath becomes edematous, and later thickened, from fibrous tissue formation.

There is a great preponderance in the reported cases of females over males. Of the twenty-four cases treated by Finkelstein, twenty were females and only four were males, four

*Read at the Annual Meeting of the New England Surgical Society at Manchester N. H. September 28, 1931.
†Patterson, Daniel C.—Attending Surgeon, Bridgeport Hospital. For record and address of author see "This Week's Issue," page 121.

teen of the females were houseworkers

Schneider states that in 135 cases where the sex was noted, one hundred and nineteen were females, and fourteen males. Two cases were bilateral. Our experience at the Bridgeport Hospital has been contrary to this, for in ten cases we have only had three females.

The symptoms and signs are quite definite and the similarity in all cases is very striking. As a rule the onset is gradual. The patient will complain of pain in the wrist of several weeks' duration and when questioned will locate the point of greatest pain over the radial styloid. They also refer to pain running up the arm and into the thumb. Pain is aggravated on abduction of the thumb, or ulnar abduction of the hand. This can be demonstrated by flexing the thumb in the palm of the hand, and with the fingers closed over it making sharp ulnar abduction. The pain gradually increases with use, as the patients continue with their work. Then weakness of the hand develops and they complain that they drop even small objects. Disability usually results. Objectively there may be slight swelling over the affected part. There is marked tenderness over the styloid process. Abduction of the thumb is restricted and forced abduction is painful. No crepitation can be felt. In our cases the symptoms and signs were so clear cut that the diagnosis was simple. The gross pathological findings, and the relief from proper treatment was so constant, that it made a most satisfactory disease to meet.

Most cases will give a history of having been treated for some time by strapping, heat, massage, etc., but with no benefit. The only non-operative treatment worthy of trial is immobilization of the thumb in a plaster cast for six weeks. This has produced cures in some cases reported, but I should think that the percentage of recurrences would be large.

The discomfort of a plaster cast on the hand for six weeks, especially in a manual worker, makes it an unsatisfactory method. Schneider reported eight cases of his fifteen cured by plaster immobilization, but the length of post-operative observation was not stated. Two of his cases in which such treatment failed to effect a cure were relieved by operation. Of sixty-six cases reported by Eschle, sixty-five were cured by operation, and one improved.

The operative treatment is so simple, and the period of disability so short, that it seems as if it should be the treatment of choice in all cases. The operation is conveniently performed under local anesthesia. A two-inch incision is made over the radial styloid, the carpal ligament and tendon sheath are exposed and incised, or a small section removed. This will allow free movement of the tendons, and produces almost instant relief of pain. The incision is then closed, and a firm bandage applied, no splinting is necessary. At the end of a week free use

of the thumb can be permitted, and in two or three weeks the patient can return to work.

There has been no instance of failure reported in the cases operated upon, though Finkelstein observed two cases that had been operated on ten and eleven months previously, in which there was still pain on pressure over the styloid process. In both instances the tendon sheath at operation had been found greatly thickened and cartilaginous in consistency. He felt that removal of the entire tendon sheath instead of a small section in these cases would have eliminated the tenderness.

While this condition is not one that is met with frequently, it is well to keep it in mind, for I know of no disease where the results of treatment are more satisfactory to the patient or the surgeon. Whenever seen it is easily recognized.

I have had six of these cases in the past few years, and Doctors Hawley and Griswold about the same number. As the histories, symptoms and findings have all been quite similar, and coincide with those mentioned above, I shall not report them in detail. They were all relieved by operation and there have been no recurrences.

DISCUSSION

DR PAUL P. SWETT, Hartford, Conn. I would just like to make a brief plea to have everyone here pay some attention to this lesion that Dr. Patterson has described so well, because I think the condition is much more frequent than is generally believed, and it certainly is a very disabling condition unless this very simple procedure is carried out.

I have been familiar with this lesion for a great many years. My first patient was a boy who operated a buffing machine on which he was engaged in grinding the surface of locks, which involved a pushing motion all day long. It occurs more frequently, however, in women, largely because they perhaps so frequently attempt to do things for which they have not accustomed themselves and have not developed the strength.

I can recall in the last two or three years doing this little operation for at least a half dozen doctors' wives, so I know it is a very common lesion and it is very generally overlooked. Many times patients have been referred to me for this mysterious thing and apparently all the medical attendants have been confused and baffled because x-ray did not show exostosis and there was still this hard little lump which they thought could not be anything but an exostosis.

PRESIDENT JOHNSON. Is there any further discussion?

DR JAMES W. SEVER, Boston, Mass. The question of spontaneous cure in DeQuervain's disease, I think, is interesting, and I feel very much as Dr. Swett does that it is a condition that has been frequently

overlooked. I asked Dr. Patterson if he had known of cases of spontaneous cure and he said he had not.

Dr. Swett has brought up the question of doctors' wives in relation to this disease. My wife had this disease as a result of playing flat ball and hitting the flat ball on the wrist. For a year and a half she had continuous disability and pain and limitation of motion but like all shoemakers' children she got no sympathy and attention.

She fell or did something or other with her wrist, with it unguarded about a year and a half later. She felt something snap. She had a little temporary pain and since then has been perfectly well.

I do not question but that she had DeQuervain's disease. In fact, I know she had now and she established spontaneous cure in some way by rupturing an adhesion which may not be the true pathology of the disease but that is what happened.

Whether it is a wise thing to wait for spontaneous cure of course is another thing. I am entirely out of sympathy of course, with it in my own family.

PRESIDENT JONASON. Is there any further discussion?

DR. FREDERIC J. COTTON, Boston, Mass. May I add two cases of spontaneous cure? One was in a doctor's wife. She was going to have it operated on had a date all set when her husband telephoned me and said it was getting well and it did.

The other was the famous guide Jack Russell who tosses about the prettiest fly I know anything about. That is one of the ways you can get this disability. He came to me a couple of years ago completely crippled. At the end of the season he was going to come down and have it operated on. That was the bad salmon season and he did not fish very much. He was chasing around finding out where the salmon had gone to all summer and he got well.

PRESIDENT JONASON. Is there any further discussion? If not, Dr. Patterson will you close the discussion?

DR. PATTERSON. With all due deference to Dr. Sever I wonder if you can call recovery in a year and a half a spontaneous cure.

I confess that I knew nothing about this condition until several years ago when my good friend George Hawley called my attention to it. From conversation with many surgeon friends I find that very few of them are familiar with the disease though they all felt sure they had seen such cases but had failed to recognize them.

The operative treatment is so simple and its results so quick and satisfactory that I think it is advisable to operate rather than to try nonoperative measures.

NEW HAMPSHIRE MEDICAL SOCIETY

ANTEPARTUM CARE*

BY M. T. EADES, M.D.†

Mr. President and Members of the New Hampshire Medical Society

THE general high quality and the advanced development of prenatal care in the United States adequately testify to its value. The laity as you are aware, are showing an increasing interest in this field of preventive medicine so that the pregnant woman today not only requests but demands a higher quality of care and medical supervision than she formerly received.

In order to cover this detailed subject briefly, I shall review and outline for you in general the system which we employ at the Boston Lying in Hospital. Prenatal care in private patients differs only in slight details although there is one vast difference between clinic and private antepartum care. In the clinic owing to the large attendance of patients and a limited medical personnel, we sometimes find difficulty in applying detailed care whereas, in private practice we frequently have difficulty, not of application but in finding the patients who are so solicitous of our advice.

Patients are encouraged to report for pre-

natal care as soon as they have passed their second missed menstrual period. At that time a careful history is recorded and a complete physical examination is performed. Also at that visit specific and general directions are given to them.

This is (throwing record on the screen) the prenatal record which is used in our clinic. As you see, it encompasses considerable detailed information. A review of this record sheet with elaboration of certain headings will serve to make it more readily understood.

Let us first consider with the patient her past medical history. The past history of infectious or contagious diseases of childhood, such as scarlet fever, diphtheria, multiple acute attacks of tonsillitis and of rheumatic fever are of great significance because of their organic sequelae. All information possible should be obtained regarding serious medical diseases of adult life with any complications which followed. Despite careful and tactful questioning, the patient may withhold information or be completely ignorant of remote or recent venereal infections. The history of the patient relative to constant contacts with tuberculosis or to her own past or present infection with the disease is not to be overlooked. These considerations may involve not only matters relating to the immediate conduct of the present pregnancy but also proper

*Presented at a part of a Symposium on Obstetrics at the Annual Meeting of the New Hampshire Medical Society at Manchester May 7, 1935.

†Hans M. P.—Assistant in Obstetrics Harvard University Medical School. For record and address of author see *This Week's Issue* p. 128.

protection and disposition of the child after it is born

The past surgical history is of importance, especially if there have been vaginal plastic or abdominal pelvic operations which not only may interfere with normal delivery but may actually contraindicate it. Also in these days of serious automobile accidents with severe injuries, a past history of pelvic trauma, especially fractured pelvis, should be carefully investigated.

The past obstetrical history, naturally, is of the greatest interest and importance to the obstetrician. This is especially true if the physician has not cared for the patient during her previous pregnancies. One should inquire very carefully into the details of the past pregnancies, their duration, any complications that may have occurred, and the details of the complications. Likewise, in previous labors, are to be noted the duration of the labor, the type, the quality, the method of termination and, if operative, the details of the operative procedures. The size of previous children, if any, should be noted as well as their subsequent history. A past history of large, deformed, or still-born children or of neonatal deaths may be of great importance in conducting the present pregnancy.

A review of past puerperal periods as to postpartum hemorrhages, retained or adherent placentae, puerperal or phlebotic infections should be as detailed as possible.

The menstrual history is of relatively less practical significance. A routine history should include data as to the periodicity of the menstrual cycle, duration, amount of flow, dysmenorrhea, etc.

This brings us to a consideration of the present pregnancy. If the patient has followed advice and appeared early in pregnancy, her complaints are usually those associated with the syndrome of physiological nausea and vomiting. This is generally well controlled by reassurance, frequent meals, high carbohydrate diet and sedatives. The expected date of confinement is calculated, based on the data of the last normal menstrual period. Various other important elements of the history at this period are those relating to the gastrointestinal tract, especially with reference to constipation which tends to become more obstinate during pregnancy. We should inquire as to any genito-urinary ailments other than frequency, which is physiological at this time. Any other symptoms of which the patient may complain are noted and thoroughly discussed at this first visit.

A complete and thorough physical examination is necessary in every case and should be performed at the first visit. The general nutrition and skeletal make-up should be noted. In the short female, showing a heavy skeletal frame and short extremities, one usually finds

associated in some degree the male type of pelvis, conversely the tall individual with thin bones usually has a more ample pelvis than the external measurements indicate. The eyes, ears, nose, sinuses, and teeth should be examined routinely. The tendency of the teeth to decay rapidly during pregnancy should be prevented as much as is possible by having a dental inspection at least twice during the gestation period, together with whatever dental repair is necessary.

The heart and lungs especially deserve to be examined with great care. We have felt at the Boston Lying-in Hospital that organic diseases of the heart and lungs complicated by pregnancy are so important that special clinics have been organized for these groups. The proper evaluation of the seriousness during pregnancy of complication of these systems if diseased is frequently such a serious problem that consultation with the internist is advisable.

Next comes the obstetrical examination proper and, of course, in early pregnancy palpation of the abdomen resolves itself into nothing more than ruling out the presence of abnormal masses or special areas of localized tenderness. However, if the patient appears late in pregnancy for her first visit, a routine palpation of the abdomen is performed. That will be described in detail a little later.

Pelvimetry is usually performed at the first visit. As a routine the intercrural, the interspinous, the external conjugate and the bischischal diameters are the external measurements taken.

The vaginal examination in early pregnancy gives not only confirmation of the presumptive diagnosis but also information as to the shape and position of the uterus, the internal contours of the pelvis and the condition of the soft parts. A careful palpation of the perineum, the cervix and bimanual examination of the vaults are necessary to rule out the presence of pelvic inflammatory or tumor masses. A knowledge of their presence is important either as to a decision for operative removal at this advantageous time, or if complications from them arise during later pregnancy. At this time an attempt is made to palpate the promontory of the sacrum with the second finger of the examining hand. If palpated a mark is made on the hand at the inferior border of the symphysis and the diagonal conjugate diameter may be measured directly, and from this the true conjugate may be easily calculated. If the promontory cannot be felt, this diameter may be considered as adequate. The vaginal examination is not complete without a specular examination. By this means the condition of the vaginal mucosa and introitus, and of the cervix may be visualized. Not infrequently polyps, the presence of scar tissue, and vaginitis, most commonly of the trichomonas variety may be read-

ily demonstrated Urethral cervical or vaginal smears on suspected cases may readily be made at this time

A word may be said about the transverse or bisacchial diameter. This, in the average American woman, is eight to eight and one-half centimeters. If a special pelvimeter for this measurement is not available, a rough test for adequacy of the pelvic outlet may be made by pushing the knuckles of the hand transversely between the ischial tuberosities. The width of the knuckles of the average hand is around eight centimeters and, while this does not constitute such an accurate method as the use of the pelvimeter, is an adequate test.

Miscellaneous tests, such as blood pressure readings, temperature, pulse and weight of the patient which are routinely taken at the first visit, will be discussed in more detail under the follow up examination. Blood specimens for a Wassermann or Hinton test are taken routinely. If specimens are reported don'tful or positive, the test is repeated. I suspect in private practice that these tests are not made so routinely as their importance demands. Certainly there is no instance in preventive medicine which gives a more brilliant prophylactic result, so far as the fetus is concerned, than the early diagnosis of syphilis in early pregnancy with prompt adequate treatment. Most State Boards of Health provide the service of free Wassermann tests and provide containers for the specimens. It would seem under these circumstances that there is no reasonable excuse for the omission of this important test.

The importance, frequency and progressive tendency of the anemias of pregnancy have recently been emphasized by the work of Strauss and Castle. Moreover they have shown how the majority can be controlled by the use of iron. While the average method of hemoglobin determination may not be scientifically accurate it provides a relative test for the clinician which is valuable. If the hemoglobin is at a high level, one can usually assume that the red blood count is within normal limits. If the hemoglobin is below seventy per cent, a red blood count is advisable and both this and the hemoglobin should be repeated at subsequent visits to study the results of treatment. Adequate treatment of anemia during pregnancy is indicated not only because of its progressive tendency in the mother but, as Strauss has shown, for prophylaxis of the fetus against anemia of infancy and early childhood. Therefore hemoglobin determination as a routine test at the first prenatal visit is recommended.

Routine urinalysis should be performed at each visit. Specific gravity, albumin and sugar determinations are made on each specimen. If albumin is present, a catheter specimen should be obtained and the centrifuged sediment examined microscopically. This completes the

physical and laboratory examinations made at the first visit.

Various matters of hygiene are then discussed with the patient. It is impossible here to go into this in detail. At this point allow me to say that this subject is not one for fads and fancies, but rather one in which we sincerely attempt to inform our patients regarding desirable methods of mental and physical conduct during pregnancy so that they may be better fitted to undergo labor and the stresses of the puerperium. Except for certain details the advice should be as valuable for the husbands as for the patients themselves. These matters of hygiene in pregnancy consist of advice relating to diet, rest, exercise, recreation, bathing, regulation of the bowels, weight regulation, and various danger symptoms which occur during pregnancy, especially as they relate to toxemia. It is generally agreed that the pregnant woman should have at least one gram of calcium per day in her diet to provide a positive calcium balance. Milk seems to provide the best source of this mineral, but in many cases the patient cannot drink sufficient milk so that calcium in other forms should be provided. It is also the consensus that, during the winter months in this geographical section, a high vitamin D diet should be provided.

For the patient who is more inquiring Dr. Irving has written an excellent handbook "The Expectant Mother" which can be highly recommended to the private patient. The United States Department of Labor also distributes free a very excellent and authentic pamphlet on the hygiene of pregnancy which may be had by writing to the Superintendent of Documents at Washington.

The patients are asked to return with increasing frequency as their pregnancy advances. In our clinic they return once a month for the first five months, at three week intervals for two months, every two weeks for the next month, and each week during the last month. This applies only to normal pregnancies. If any complication develops the patients are seen at as frequent intervals as is considered necessary by the physician in attendance.

On each return visit, a short history of the patient is taken regarding any complaints, and specific inquiries are made as to regularity of the bowels, the activity of the child, bleeding, toxic symptoms and the occurrence of localized pain. Routine blood pressure determination, weight records, and urinalysis are made at each visit. Any blood pressure reading above 140 mm/Hg systolic, or above 90 mm/Hg diastolic, we have come to regard as evidence of circulatory abnormality whether it be due to essential hypertension, toxemia, or chronic nephritis.

Abnormal increase in weight is usually one of the earliest signs of toxemia of pregnancy.

It is also common in hydramnios and multiple pregnancy. It is usually due, however, to an indiscretion in diet or otherwise an evidence of the tendency of the pregnant woman to gain unduly. A twenty to twenty-five pound gain during pregnancy is considered normal and the weight increase of the normal patient can usually be held within this limit with proper dietary supervision.

As pregnancy advances a history of increasing growth of the abdomen is commonly volunteered by the patient. We do not routinely palpate the abdomen until the beginning of the seventh month of gestation unless there is some reason to suspect abnormality. This is suggested either by lack of consistent abdominal enlargement, or by a rapid increase in size over a four weeks' period during the fourth to the seventh months. At the seventh month the abdomen is carefully examined. The height of the fundus above the symphysis pubis is measured to note whether the size of the uterus is commensurate with the expected date of confinement. The position and presentation of the fetus are mapped out, although it is too early at this examination to obtain accurate information concerning cephalopelvic relations. The rate of the fetal heart sounds and the location on the mother's abdomen of their greatest intensity is recorded. The chief value of the palpation at the seventh month of pregnancy is that this represents the optimum time, not only for the diagnosis but also for the correction of malpresentations, especially breech or transverse presentations. The unfavorable presentation may recur after manipulations but this is the most favorable period for the performance of any necessary conversion maneuvers.

During the ninth month at each weekly visit, palpation is performed on an average of every two weeks. Except with primiparae it is performed together with rectal examination until the head reaches full engagement. This keeps us aware of those primiparae who enter labor with a high or floating head, and gives us warning so that they may be more carefully observed during their labors. Vaginal examinations except under aseptic precautions are not made during the last month of pregnancy. We feel that in routine prenatal care one can satisfactorily determine the descent of the head and condition of the cervix by rectal examination without the potential danger of rupture of the membranes followed by possible infection as is involved by vaginal examinations. However, in abnormal conditions or where the desired information cannot be elicited by rectal examination, vaginal examinations following aseptic preparations are employed.

I should like to digress briefly regarding two of the most commonly encountered abnormalities during the prenatal period. These are first, the bleeding cases, and secondly, the incipient

toxemic conditions, of which the latter represent only a step over the normal border. In the abortion group with bleeding early in pregnancy we do not attempt hospitalization unless the patient is in poor condition or the bleeding profuse. Our treatment is conservative and consists entirely of rest in bed with opiates administered only because of pain. It is not felt that these drugs influence the ultimate outcome of the miscarriage. If in this group there is any question of ectopic pregnancy these patients are referred to the hospital for diagnosis and treatment. Dr. Arthur Heitig at our hospital is doing some interesting pathological studies on the causes and pathology of abortions. He is extremely anxious to obtain specimens, and if any of you would be interested in sending him such material preserved in 10 per cent formalin solution, Dr. Heitig will send you a complete report of his studies on the specimen received. In most instances he is able to determine definite pathology of the fertilized ovum and it has been of great value in helping us to understand something of the pathology of early abortions.

Hemorrhage and its pathology in the last trimester of pregnancy, we regard more seriously. These patients should be hospitalized as promptly as possible and we constantly teach our students not to examine these cases vaginally or to contaminate the vagina in any way. Once in the hospital preliminary preparations for transfusion are made, and diagnostic vaginal examination may then be carried out and the proper treatment instituted. We feel that an attempt to pack a bleeding case at home is an extremely dangerous procedure which may lead to the loss of the patient's life later on from infection. Infection is quite as often a danger with these serious bleeding cases as the actual loss of blood itself.

The management of the beginning toxemic condition deserves mention. At our clinic any patient during pregnancy who shows a systolic blood pressure above 140 mm. Hg, or a diastolic pressure above 90 mm. Hg is considered a potential toxemic and is referred to the hospital for routine study. We cannot always in private practice hospitalize this group of patients but we can at least start dietary and eliminative treatment, and keep the patient under closer observation. The earlier treatment is started, in general, the more chance there is of at least controlling the condition for a period. Blood pressure observations and urinalysis on such patients should be made at least once a week. The ultimate disposition will depend of course on whether the patient responds to treatment, or the toxemia becomes worse in spite of treatment. In the latter case hospitalization is indicated, for here the patient is under continuous observation and treatment more readily controlled.

MISCELLANY

DOCTOR EDWARD HENRY THOMPSON

Dr Edward Henry Thompson who was a practicing physician in Hampton N. H. for thirty-one years, died at his home on the Lafayette Highway on November 20 1935

Dr Thompson was born in Winthrop Maine in 1861 son of Henry and Mary Snow Thompson. His early education was obtained in the Maine schools and he graduated from the Edward Little High School in Auburn. He then attended Yale graduating with the famous class of 1887. Dr Thompson received his medical education at Dartmouth Medical School graduating in 1896. He then attended the Post-Graduate College of Physicians and Surgeons in New York City now the Medical School of Columbia University. He served his Internship at Bellevue Hospital.

After having experience as a pharmacist in Wolfeboro Dr Thompson moved to Hampton. He soon enjoyed a large practice. Among his patients were residents from many parts of New Hampshire who

vacationed at Hampton Beach. For the last few years, he also had an office on Beacon Street Boston.

Dr Thompson was a member of the American Medical Association and the New Hampshire Medical Society, the Masonic Blue Lodge, the Knights Templars and the Order of Mechanics. He was a 3rd degree Mason.

All of his life Dr Thompson was an omnivorous reader and he had a large library. He was a constant student of medical progress and deeply interested in classic and English literature.

Dr Thompson is survived by his widow, the former Alice Higgins of South Portland, a son, Leon, a daughter, Mrs. Isabelle Williams, and five grandchildren.

THE NEW HAMPSHIRE MEDICAL SOCIETY
ANNUAL MEETING

The next annual meeting of the New Hampshire Medical Society will be held at the Hotel Carpenter in Manchester, New Hampshire on May 26 and 27 1936.

Please notice the change in dates.

MAINE NEWS ITEMS

CENTRAL MAINE GENERAL HOSPITAL
LEWISTON, MAINE

Graduate Teaching Clinics were held November 15 1935 and December 20 1935. At the November 15 clinic there were case presentations from 9:30 A.M. to 12 noon led by Dr. J. C. Aub. 2:30 P.M. to 5 P.M. ward walks and talks and case discussions and at 8 P.M. a paper by Dr. Ann on Diets. At the December 20 clinic the discussions were led by Dr. W. R. Morrison of Boston who presented as the evening paper Bleeding Ulcers of the Stomach. Coming clinics are announced as follows:

January 24 1936—Dr. S. J. Thannhaner: Functional Tests in Dietary Treatment of Liver Disorders.

Dr. Joseph Pratt: The Neuroses.

Dr. Jacob Schloss: Newer Methods in Diagnosis of Gastric Diseases.

February 28 1936—Dr. William O. Quinby: Daily Problems in the Treatment of Patients with Genito-Urinary Disturbances.

March 27 1936—Dr. William B. Castle: Medical Aspects of Diseases of the Colon.

April 17 1936—Dr. Soma Weiss: The Clinical Use of Sedatives with Particular Reference to the Barbituric Acid Derivatives.

May 22 1936—Dr. Otto J. Hermann: Some Aspects of the Management of Fractures.

On November 27 1935 a regular meeting of the Sagadahoc County Medical Society was held in Bath, Maine. The paper of the evening was read

by Dr. Edward H. Risley of Waterville, Maine. The subject was The Treatment of Postoperative Complications with Especial Reference to the Use of the Duodenal Tube.

EDWARD H. RISLEY, M.D.

THE CONTROL OF PNEUMONIA

Six men, representing six important organizations engaged in promoting the people's health left a meeting in Center Street, New York, recently after having made plans for the control of pneumonia in New York State. Passers-by would not have given them a second look—they were quite ordinary looking men. Their discussion raised hope of saving 3,000 lives per year. As they stood for a moment on the corner a siren screamed and the gas company's emergency wagon rushed past to resuscitate an asphyxiated victim. One life—much excitement. 3,000 lives no fuss.

Joining hands for a state-wide organized attack on pneumonia are the following: The Medical Society of the State of New York, the New York State Department of Health, the Metropolitan Life Insurance Company, the Commonwealth Fund and the New York State Association of Public Health Laboratories. The Rockefeller Institute is cooperating in an advisory capacity. One of the weapons in the attack on this disease will be informing the general public that a case of pneumonia is just as much an emergency as asphyxiation and if a siren is not blown it should be.

THE TREATMENT OF THE POSTHERPETIC NEURALGIAS

BY CHARLES METCALFE BYRNES, M D *

THERE are few types of neuralgia which offer greater therapeutic difficulties or in which the choice of effective treatment demands so accurate a knowledge of anatomy as do certain forms of the postherpetic neuralgias

Antineuralgic drugs and the various forms of physical therapy employed in the treatment of herpes zoster are of little service in the residual neuralgias. Although Ruggles¹ and Phillips and Morginson² have obtained prompt relief of the acute attack by the use of sodium iodide, I have found it of no benefit in the chronic neuralgias. Pituitrin, also a popular remedy in the acute disorder has no effect upon the late neuralgias. Ravaut³ finds autohemotherapy helpful in both the acute and chronic affection.

The statement by Lhermitt, that a history or laboratory evidence of syphilis is obtained in 72 per cent of the cases of zoster, has been responsible for the adoption of antiluetic therapy, and there are records of its apparent efficacy in acute zona, although the Wassermann test was negative. Milian⁴ claims to have relieved a postherpetic neuralgia with four intravenous doses of salvarsan, but the drug was quite ineffectual in one of my patients with lumbosacral neuralgia of this type.

Physical therapy in the form of electricity, heat, light and baths has its advocates. Stowell⁵ recommends the galvanic current and the mild static spark. Keichline⁶, after three radiations of the gasserian ganglion, ten days apart, claims to have completely relieved a neuralgia of four weeks' duration. Bailey⁷ finds the x-ray most effective when used shortly after the appearance of the eruption, but sometimes beneficial in the chronic affection. Lust⁸ has also obtained good results from its use, although diathermy is now more popular. Louste and Juster⁹ have found the mercury-quartz lamp of benefit. Pyrexia is said to possess no merit.

Notwithstanding Bailey's statement that postherpetic neuralgia "is not susceptible to surgical relief" there is some evidence that even peripheral interruption of the nerve impulse is, at times an effective measure, but inasmuch as the lesion is situated in the ganglion, it is difficult to account for the relief which is sometimes obtained from the peripheral operation. Nevertheless Wilfred Harris notes that posterior rhizotomy is not always successful.

Inasmuch as one or more spinal as well as the homologous cranial nerve ganglia may be simultaneously affected by the herpetic virus, a special knowledge of anatomy is sometimes essential in order to adopt an effective operative

procedure. It is, therefore, desirable to consider the postherpetic neuralgias according to their anatomical distribution.

POSTHERPETIC TRIGEMINAL NEURALGIA. The ophthalmic and maxillary branches are most commonly affected. Drugs and the various forms of electrical treatment often afford only temporary relief and the radical operation upon the sensory root is not always successful. Adson¹⁰ found total division of the root ineffectual in two cases, and a third patient was only partly benefited. According to Bailey, Peet also failed to procure relief by this procedure. Patrick¹¹ has relieved pain by the injection of alcohol into the supra-orbital nerve, and Ely¹² has had a like experience. The uniform success I have experienced with the superficial and deep injections of alcohol into the trigeminal nerve or ganglion in a large number of cases of the douloureux encouraged the adoption of this method of treating the postherpetic neuralgias. It is well to inform the patient, however, that the affection is quite different from major neuralgia and that the injection is not uniformly successful. The following clinical records indicate, however, that the method possesses some merit.

C F B, male, aged sixty-five, referred April 2, 1918 had suffered, several years previously, from herpes ophthalmicus gangrenosus of the right forehead. A few scattered vesicles appeared also on the right cheek below the eye. The neuralgia was largely confined to the forehead but, during a severe attack, often radiated into the cheek and upper lip. He was then taking as much as forty grains of acetanilid daily, but this had only made his suffering "endurable", and continued use of the drug had resulted in a secondary anemia and marked cyanosis of the lips and fingertips.

Alcohol injection of the supra-orbital and infra-orbital nerves produced the desired anesthesia in their respective cutaneous fields, but the customary edema was responsible for a dull, aching pain over the forehead, this persisted until the swelling subsided, but there were no further neuralgic attacks. Two months later the patient wrote as follows: "While I am never entirely free from pain over my right eye, it is so mild that if I am reasonably entertained I forget about it. I take no medicine. I have less pain now than I had when I was taking forty grains of acetanilid daily. The relief your treatment gave me was very great." A letter from his wife in March, 1935, stated that the patient died in 1932, fourteen years after treatment, and that "he felt that you had saved him years of pain, although he was never entirely free from head aches."

A P, male, aged eighty-four, referred April 4, 1928 by Dr G Timberlake, of St. Petersburg, Fla., because of "pain over the left forehead and in the left cheek." The neuralgia, which had followed an attack of herpes ophthalmicus three years previously, occurred spontaneously or was initiated by a light touch upon the forehead or a sudden change in atmospheric conditions.

*Byrnes, Charles M.—Associate in Neurology, Johns Hopkins University School of Medicine. For record and address of author see "This Week's Issue" page 128.

because of its simplicity and safety, paravertebral injection of alcohol might be done with reasonable assurance of relief. Even though it is not always certain that the injection can be made into the affected ganglion, the procedure is sometimes effective. Inasmuch as posterior rhizotomy is not always successful, cordotomy should be the operation of choice. Recently, Dogliotti²¹, Stern²², and Greenhill and Schmitz²³ have relieved persistent pain in the lower thoracic and lumbosacral nerves by the subarachnoid injection of alcohol, and Dogliotti has used the method with success in one case of postherpetic intercostal neuralgia. The procedure is, in reality, a chemical rhizotomy. The injection is made with the posture of the patient such as to place the posterior roots uppermost, when the alcohol, being of lighter specific gravity than the spinal fluid, ascends to this upper level where it is said to affect the sensory roots alone. The method is not without danger and should be employed only by those skilled in this technique.

POSTHERPETIC NEURALGIA OF THE LUMBOSACRAL NERVES. Because of the large and important motor component of these nerves, neurotomy and paravertebral injections have here, a restricted use. Alcohol might be safely injected into the first, second and third lumbar intervertebral foramina, but below this level the injection of even one foramen is likely to cause undesirable motor complications.

Peripheral interruption of the efferent path in the neuralgias of this region offers many difficulties and is rarely successful. Various measures were ineffectual in one of my patients suffering from neuralgia of the first, second and third sacral nerves. Injection of alcohol into the first sacral foramen produced numbness of the heel and part of the tendon Achilles, but failed to relieve the pain. Because of the likelihood of implicating the bladder and rectal sphincters, the second and third sacral segments were not injected. Epidural injections of novocaine followed by 60 cc of normal salt solution failed to procure any appreciable relief, and in infiltration of the sciatic nerve with novocaine and salt solution was also unsuccessful. Salvarsan, sodium iodide and pituitrin had no effect upon the pain and, because of the patient's advanced age, subarachnoid injection of alcohol and cordotomy were not recommended.

Thus, although the postherpetic neuralgias are particularly resistant to medical and surgical treatment, the statement that they are not susceptible to surgical relief does not seem warranted.

Drugs and other measures used in the treatment of the acute attack are of little use in the chronic neuralgias. Diathermy and the x-ray are said to be of some value.

Although the lesion is in the ganglion, periph-

eral interruption of the nerve impulse by the injection of alcohol procures relief with sufficient frequency to warrant its adoption before resorting to more radical measures. Should this be ineffectual, paravertebral injection of alcohol, in suitable cases, might be practiced.

Inasmuch as posterior rhizotomy is often unsuccessful the subarachnoid injection of alcohol in the thoracic and lumbosacral neuralgias seems preferable to root section and should be practiced before recommending cordotomy.

That the geniculate ganglion is subject to invasion by the herpetic virus, and that the lesion might secondarily implicate the facial nerve with the production of a facial palsy rest upon clinical and pathological demonstration. There is no proof, however, that the herpes virus which may occur independently or accompany the facial palsy, is due to the geniculate ganglion lesion, and I am of the opinion that, in this syndrome, the herpes is due to simultaneous involvement of the ganglia of the vagus, glossopharyngeal, or trigeminal nerves. Thus, relief of these postherpetic otalgias is not likely to be procured through operations upon the geniculate ganglion or the nervus intermedius.

THE HINTON TEST*

III Its Clinical Value

BY AUSTIN W CHEEVER, M D †

ALL who have been dealing with syphilis for a number of years have come to realize the inadequacies of the Wassermann test. Although this has been one of the greatest diagnostic aids in the whole field of medicine, yet in the latent and late stages when the greatest dependence must be placed on a blood test, it fails us in a fairly high percentage of cases. Consequently, the greater delicacy of the Hinton test is of great value to those who use it, especially since this greater delicacy has not been at the expense of dependability, for false positive Hinton tests are definitely fewer in number than false positive Wassermans or Kahns.

The following is a report of my personal experience in private practice with the Hinton test since its inception in 1927. Hospital cases have been omitted as they were found simply to augment the numbers. Only the cases of patients who have had the Wassermann, Kahn, and Hinton tests made simultaneously have been included in this study, otherwise, there has been no selection. Some cases, therefore, date as far back as 1918 and would be expected to have completely negative tests, while others are very recent and are still under intensive treatment. The comparative results of the tests are given

Groups 2 and 3, totaling forty-eight cases, show the superiority in sensitivity of the Hinton as compared with the Wassermann, and group 3 (twelve cases) the superiority of the Hinton and Kahn over the Wassermann, the Kahn being somewhat more sensitive than the Wassermann. No single blood test as yet available is quantitative, but the use of the three tests at the same time gives a sort of quantitative measure which the average patient can understand, and he can be made to feel definitely encouraged when one or two of the tests have become negative and so be persuaded to continue treatment if the physician feels that it is necessary.

One case in point is M. W. with early syphilis in March, 1931, with all three tests positive. After regular intensive treatment, in November, 1931, the patient showed Wassermann and Kahn negative, only the Hinton remaining positive. In March, 1933, the Hinton was doubtful, and in September of that year, the Hinton, also, became negative. This greater persistence of positivity of the Hinton made it possible to keep the patient under treatment almost two years longer than would have been probable had the Wassermann alone been used. Not all cases are ideal as this one, because now and then one or more tests may become positive after

TABLE 1
COMPARATIVE RESULTS OF BLOOD TESTS ON 143 CASES OF TREATED SYPHILIS

Group	1	2	3	4	5	
Wassermann	—	—	—	+ or ±	—	
Kahn	—	—	+ or ±	+	+ or ±	
Hinton	—	+ or ±	+	+	—	
Totals	74	36	12	19	2	143

in table 1 which shows the results of the latest blood examination.

Group 1, consisting of cases with all three tests negative, totals seventy-four, approximately one-half of the cases studied. These all occur in patients who have had considerable treatment. This is an answer to the question raised when the Hinton test first began to be used as to whether it is not so delicate that it might be expected to remain always positive. Most of these patients who have reached this stage have had, for varying periods, positive Hinton tests while one or both the Wassermann and Kahn had become negative. In other words, they have passed through the same condition as those shown in groups 2 and 3.

having been negative, but there is usually a strong tendency toward this type of progressive improvement.

In group 4 (nineteen cases) where all three tests are positive there is represented obviously a group of patients whose treatment to the present has been inadequate, or who fall into the group of the seropositive.

As a laboratory aid during treatment, the Wassermann test with only nineteen positives in the 143 cases falls far behind the Hinton which shows forty-eight additional (sixty-seven total) positive reactions. In other words, the efficacy of the Hinton in this group of cases is three and one-half times that of the Wassermann. The Kahn reaction was somewhat better than the Wassermann in that it gave fifteen more positive cases (total thirty-four), making it about one-half as sensitive as the Hinton.

There were only two cases with a negative

*Read before the Fifth Congress of the Pan American Medical Congress, March 14-30, 1934.

†Cheever, Austin W.—Assistant, Department of Dermatology and Syphilology, Harvard University Medical School. For record and address of author see "This Week's Issue," page 123.

Hinton in the face of any other positive These were two isolated doubtful Kahns. It is possible that these are truly false positive Kahns as the apical fluid in both instances was negative and all three tests had previously been negative for six years.

One half of these cases have had tests of the spinal fluid made. In no instance was there any positive spinal fluid finding in the face of a negative blood Hinton test. This agrees with findings of Hinton and Berk¹, who compared the blood and spinal fluid in 787 cases of syphilis, and found not a single instance of definite pathology in any spinal fluid where the blood Hinton was negative, although in fifteen cases the Hinton was negative and the spinal fluid doubtfully positive.

It is obvious that the figures will be somewhat different when the tests are used for detecting unsuspected syphilis. For the purpose of comparison, I am adding some unpublished figures of Hinton's

a group of 1110 patients in whom syphilis seemed extremely unlikely.

In certain cases the Hinton test is of extreme importance in arriving at a correct diagnosis as in the following case. A patient whose only complaint was a slight feeling of tightness in the chest and the knowledge of the death of one or two of his friends from angina pectoris consulted a leading diagnostician whose opinion was that the patient was overtired and was smoking too much. A routine blood test was done and the Hinton was positive and the Wassermann negative. A subsequent history was obtained of gonorrhea many years earlier but no syphilis had been suspected though the attending physician had noted that there was some hardness about the mentus. It is probable that there was an unnoted meatal primary and the picture puzzle is now complete a probable meatal primary a positive Hinton and symptoms consistent with aortitis. The prognosis

TABLE 3

COMPARATIVE RESULTS IN 4864 CONSECUTIVE ADMISSIONS TO SELECTED HOSPITALS IN MASSACHUSETTS

	Total Number Examined	Positive Wassermann	Percentage of Positive Wassermann	Positive Hinton	Percentage of Positive Hinton
Cancer cases	3193	129	4.03	204	6.37
Tuberculosis cases	475	15	3.15	34	7.15
Pregnancy cases	1191	8	0.67	16	1.34
Total	4864	152	3.12	254	5.22

In a total of 4864 blood tests routinely taken in groups of cancer, tuberculosis, and pregnancy patients, 152 (3.12 per cent) positive Wassermann reactions were found as compared with 254 (5.22 per cent) positive Hintons. This shows a marked superiority of the Hinton over the Wassermann in detecting unsuspected syphilis.

When the Hinton test first became available for use the question was immediately raised as to whether the increased delicacy would not be accompanied by a great increase in the number of false positives, in other words if the test were not going to be too delicate for practical use in diagnosis. This figure of 1.34 per cent of positive Hinton tests in as large a number of pregnant women as 1191 can scarcely be expected to contain many false positives. Mingr² has recently published figures on a group of 750 positive Hintons in which he found one false positive. Cheever and Splaine³ found what appeared to be two false positive Hintons as compared with seven false positive Wassermans in

under antisypilitic treatment at this time should be excellent whereas it would have been very poor had the condition gone on to the point of clinical recognition.

Summary. It has been shown that in a group of 143 patients with treated syphilis the Hinton has proved to be twice as efficacious as the Kahn and three and one-half times the Wassermann. In detecting unsuspected syphilis in a group of approximately 5000 cases of cancer, tuberculosis, and pregnancy the Hinton was found to be nearly twice as efficacious as the Wassermann. False positive Hintons are shown to be extremely few in number.

THE TREATMENT OF ARTHRITIS WITH GOLD SALTS*

BY ROBERT TITUS PHILLIPS, M D †

GOLD salts were introduced as a method of therapy in arthritis by Forestier in 1928. This investigator has published several papers on this subject, the latest¹ reporting his experience with this method on over five hundred and fifty cases during the past six years. In a series of twenty cases studied in the Out-Patient Arthritis Clinic of the Boston City Hospital from October, 1934, to June, 1935, reactions were found to be so frequent and, in several cases, so distressing that a note of caution in the handling of this drug seems indicated.

The aurothiomalate of sodium (Myochrysine) ‡ was used in our clinic, according to the technique described by Forestier. Our patients included nine with atrophic arthritis, eight with hypertrophic, two with peripheral neuritis, and one with subdeltoid bursitis. Treatments were carried out at weekly intervals. A total of 162 intramuscular injections were given, an average of eight per patient. The largest number given one patient was twenty-four.

Dosage was started with 0.050 Gm. Injections were made in the deltoid, at first, later in the buttock. Subsequently, in half the cases, the dose was reduced to 0.020 or 0.010 Gm because of unfavorable reactions. A few patients tolerated doses of 0.100 Gm without toxic symptoms. In no case was a greater amount given. Occasional injections with normal salt solution readily convinced us that the patients knew when Myochrysine was omitted.

Six patients received a total exceeding 150 Gm. The series was finally discontinued because of the increasing number of unpleasant responses, evidence of improvement being infrequent or uncertain.

Sedimentation rates according to the Westergren method were repeatedly done on all patients. Significant changes in sedimentation time were not observed.

Of the twenty patients, six, including two with atrophic, two with hypertrophic, and two with peripheral neuritis, reported subjective improvement. Another group of six refused further treatment because they claimed it made them worse. This latter group, together with the eight remaining patients, all experienced local or generalized reactions.

REACTIONS

The various types of reactions which this writer believes are attributable to gold therapy include the following:

*From the Arthritis Clinic, Boston City Hospital, the Department of Medicine, Tufts College Medical School and the First and Third (Tufts) Medical Services, Boston City Hospital.

‡The Myochrysine used in this study was supplied by Merck & Co.

†Phillips, Robert T.—Instructor in Medicine, Tufts College Medical School. For record and address of author see "This Week's Issue" page 123.

Headache
Dizziness
Sleepiness
Tinnitus
Fever
General malaise
Loss of weight
Nausea
Epigastric distress
Vomiting
Pruritus
Dermatitis with vesicle formation, especially on the hands, fingers, forehead, and the buccal mucous membrane
Anesthesia of the tongue
Sore tongue
Jaundice
Local swelling with formation of hard painful lumps at site of injections

CASE NOTES

CASE 1 A G Aged thirty-eight Three treatments Rheumatoid arthritis Spine and shoulder girdle Two years' duration Blood sedimentation rate, 46 Thorough investigation during a six-week hospital admission revealed no serious organic pathology. Following the third injection of Myochrysine, developed extreme jaundice, with loss of five pounds in one week. Nausea and vomiting. Forced to remain in bed two weeks. Symptoms improved in one month with injections of normal saline solution.

CASE 2 M F Aged forty-eight Eleven treatments Rheumatoid arthritis Six years' duration Fusiform swelling of hands, fibrous ankylosis of wrists and left elbow Blood sedimentation rate, 28 After the fourth treatment, headache, epigastric distress, general malaise. Refused further treatment when generalized pruritus followed eleventh injection.

CASE 3 D G Aged forty Twenty-four treatments Rheumatoid arthritis (Strümpell Marie) Five years' duration Blood sedimentation rate, 14 Hard lump at site of injections No improvement.

CASE 4 J W Aged twenty-nine Nineteen treatments Rheumatoid arthritis Fusiform fingers

Case 4. J W showing lesions characteristic of typical psoriasis which developed following intramuscular injections of gold salts. This patient, prior to treatment, never suffered from skin lesions of any kind whatever.

Ankylosis of right elbow and two fingers Two years duration After eighteenth treatment, approximately fifty slightly elevated brownish red maculopapular lesions two to ten millimeters in diameter appeared upon the abdomen Sore tongue with vesicles on upper gums Felt improved on Myochrysin and desired to continue. Dose cut down but rash persisted soon manifesting itself as typical psoriasis persisting and spreading under the breasts and on the abdomen This patient repeatedly stated that the Myochrysin diminished the pain and stiffness The skin lesions have continued without change

CASE 5 T. H. Aged forty-five Eight treatments. Peripheral neuritis, left arm Ten years duration Blood sedimentation rate 14 Symptom free with complete recovery after eight injections.

CASE 6 D. R. Aged forty-eight Six treatments Rheumatoid arthritis Blood sedimentation rate 15 Pain and swelling of hands Six months duration Developed rash on forehead and generalized pruritus which readily subsided Swelling and pain at site of injections. Felt definitely improved on treatments

CASE 7 B. M. Aged forty-one Sixteen treatments. Osteoarthritis Blood sedimentation rate 9 Pain in both knees and neck Four months duration Headache, nausea, huzzing in the ears following second injection Lump in arm at site of injections also in buttock after each treatment. Complained of tongue going to sleep since being on treatment. No improvement. This patient had a strongly positive Wassermann and other antilaetic therapy was instituted her joint symptoms rapidly subsided

DISCUSSION

The French writers emphasize the necessity of long continued treatment with gold salts i.e. at least two series totaling 150 grams each with an interval of several weeks. It is suggested that this type of therapy should be continued at least one or two years in a manner comparable to that pursued in antineoplastic treatment. I am of the opinion, however, that even with small doses of gold salts, the untoward reactions apparently exhibited by many patients constitute a hazard which should make

us extremely cautious in undertaking a therapeutic program based on the use of gold salts. In view of the uncertainty which attends our knowledge of the exact manner in which gold operates in the human economy, it would appear that the more rational approach to the relief of arthritis is through a program based upon a restitution of what Penberton² has so succinctly termed the patient's "physiologic equilibrium." Such a program, embodying as it does "wide angled vision" in the consideration of the varying factors which seem best calculated to achieve results in the treatment of this vast family of diseases known as rheumatism, has recently been published³

CONCLUSIONS

1 Observations on the treatment with gold salts of twenty patients suffering from various forms of arthritis are reported

2 Fourteen patients responded poorly to this method of therapy The various types of untoward reactions are enumerated

3 I believe the hazard to the patient treated with gold salts is such that judicious care must be exercised in the selection of cases and in their subsequent management. Personally I do not, for the present at least, feel competent to handle this drug to the advantage of the patient

4 The whole subject of gold therapy in arthritis suggests a further emphasis on basic physiologic principles in the treatment of a disease group which has yet to yield consistently, at any rate, to specific therapeutic measures

THE MEDICAL, LEGAL, AND ETHICAL CONNECTION BY PHYSICIANS WITH CASES OF MALPRACTICE WHICH HAVE NO CRIMINAL FACTORS*

BY F. W. ANTHONY, M.D.†

THE subject for consideration this evening is "The Medical, Legal and Ethical Connection by Physicians with Proved or Suspected cases of Crime or of Malpractice. Part 1 Cases where crime is a factor. Part 2 Cases where crime is not a factor."

The gentleman who has preceded me has spoken on Part 1. I am to discuss an entirely different phase of the subject, that of Part 2—the medical and ethical aspect of the physi-

cians' association with cases where, with no criminal factor involved, malpractice is known or suspected to have taken place.

This includes matters connected with the subsequent treatment of cases previously in the hands of another physician, with consultation work in cases such as those under consideration and with the relationship of the physician to Court procedures.

It may simplify matters and help clarify thought if, before we enter upon the discussion, we grant certain things

1. That physicians generally do refuse to testify against others

*Read before the Pentucket Association of Physicians and Surgeons from the Essex North District on June 20, 1935.
†Anthony Francis W.—Member of Staff, Gale Hospital, Haverhill, Mass. For record and address of author see "This Week's Issue," page 128.

2 That in some cases this seems to impose an injustice

I will later discuss these two admissions

I will first consider the "treatment of cases previously in the hands of another physician." This is the time at which many a suit is started, very often by a remark made inadvertently by the second physician and, almost always, with no thought that it will fall upon fertile soil and become the cause of much trouble later. Not alone a remark but a shrug of the shoulders or even a significant look may be sufficient to be the starting point of trouble. Under circumstances such as these a physician should remember that he is seldom in possession of all the facts regarding the earlier treatment of the case, the difficulties that presented themselves, the accidental happenings which sometimes may not be prevented, and lack of cooperation on the part of the patient or his neglect or refusal to carry out definitely given directions. Criticism, therefore, is both foolish and dangerous.

These remarks apply equally and with the same force to the acts of the consultant who may be called to see the case while it is in the hands of the second physician.

Suppose, however, that the second physician is one of standing and good training and that he is convinced that he has received sufficient evidence to cause him to form a well-founded opinion that his patient has suffered grievously from real malpractice, what is then his medical and ethical duty to the patient who has come to him in good faith to secure his opinion and to receive such treatment as he can give for the relief of a condition either painful, disfiguring or disabling? I think we would all agree on one thing, namely, that, provided the first physician is out of the case, the second physician should give the patient all the treatment within his power in an attempt to restore him to a better condition. I believe also that the patient is entitled to a definite statement of the established physical facts in his case. I do not believe that the physician is medically or ethically obligated at that time to voice criticism of the methods used by another.

Let us now assume that another phase has arisen. The person who actually has, or thinks he has, suffered from malpractice consults an attorney and the attorney comes for a statement of facts and opinion. Here comes a difficult situation. Why does the physician hesitate to give freely the facts and his opinion? There are several reasons. First, a reason of minor importance, the thought that a similar happening may at some time come to him personally with consequent loss of prestige and with perhaps financial loss, secondly, another minor reason, the natural feeling of solidarity. This feeling is not confined to the medical profession alone but exists in others as well. This may be illustrated by an experience of my own

a number of years ago, when an attorney received a fee for an examination made by me of one of his clients in a distant city, and after two years I was unable to secure this fee. I was finally forced to seek legal aid only to learn that not an attorney in the city where I lived would try to collect the money from a "brother lawyer." I was forced to go to another city where an attorney of high standing, after assuring himself that the action was not taken against an attorney in the city in which he resided, agreed to and did collect the fee. Even clergymen are loath to take action in cases in which misconduct on the part of some gentleman of the cloth seems probable. The feeling is much the same that exists in a family, as was illustrated in Boston a few years ago when a policeman, attempting to arrest a man who was beating his wife, found himself in the midst of trouble when both husband and wife turned upon him.

In addition to these minor reasons there are more important ones. It is seldom that there is in the possession of a physician so much evidence that he can be sure that he has all the facts and that there is no reasonable defense for the quality of the work that has been done. Therefore it occurs to him when the evidence for the defense is all presented that he may find himself in a very difficult spot.

Another reason is that, not infrequently, while malpractice may exist, the end result, not so good as it should have been with proper treatment and care, is, none the less, not nearly so bad as is represented by the patient, the symptoms being exaggerated and staged for purposes of financial gain. This again causes him to hesitate.

But the most important reason of all is that the physician may have reason to entertain grave doubts whether it is the desire and intention of the attorney to learn and have set forth in court the real facts in the case. Experience has taught that the majority of attorneys consider that it is their duty to set forth and maintain before a court or a jury only such facts as serve to support their contention, these being based almost entirely upon what their client desires to maintain. A physician inexperienced in court proceedings, but with, perhaps, an occasional bitter experience, dreads the ordeal of being permitted to state only such facts as tend to support a contention, and to have to submit upon cross-examination to attempts to belittle his training or experience, his qualifications as a witness, the accuracy of his observations, the value of his prognosis, finding himself limited by the laws of evidence in what he may say and entangled in the meshes laid by a shrewd attorney who insists upon an answer "yes" or "no", or, after stating the most extreme improbabilities, inquires if such a situation is not "possible." To those of us who have met repre-

sentatives of this type of attorney in the courts for many years and who are fully aware of our own rights as witnesses, and whose feeling in stead of that of fear is of unqualified contempt for the methods used and the man who stoops to them, these situations present a challenge rather than a humiliation, but the ordinary practitioner, dreading to find himself in a situation of this sort, refuses to appear voluntarily or to furnish information which may entangle him in legal matters. Not convinced that the attorney will present to the court the facts as he finds them without regarding how they may affect the supposed interests of his client, the physician is apt to take what is for him the easiest course and say nothing.

I will now speak of the second matter that we granted at the start of this talk, namely that in some cases the refusal to testify seems to work an injustice. A case in point is one in which it is my belief that the failure to recognize and therefore to treat a physical condition that had arisen, combined with the failure adequately to follow up the case afterwards, caused a disability that removed permanently from the ranks of the employed, a man who normally would have had years of usefulness ahead of him. Were it not for relatives he would now be an object of public charity and, in his later years, he may be such an object. Another illustrative case is one where it is stated on good authority that an alleged surgeon, unqualified for the work he attempted, operated in such a manner as to cause most serious injury to the patient.

Such cases while not frequent, none the less undoubtedly exist, and I doubt if anyone, except one of base nature and absolutely selfish personality, would maintain that there should be no recompense for the patient who is so unfortunate as to be forced to go through with such an experience. There must be some plan devised by which justice will be done to the patient, the physician, the attorney and that part of the public which is directly interested. The initiative will have to be taken by the medical profession.

Similar action has been initiated and carried to a satisfactory conclusion in a somewhat similar situation. Over thirty years ago when I began to emerge from the obscurity that surrounds the youthful practitioner and to enter upon a line of work that has kept me since that time more or less in the courts of the Commonwealth, there existed a condition of affairs that was intolerable. It was then the custom in civil cases for two physicians, one representing the patient and his attorney, and the other the attorney for the defense, to meet and examine the plaintiff. No information other than the most superficial, and sometimes none at all, was given by the patient's physician. At the close of the examination, the physicians separated, one per-

haps jubilant that he had concealed important facts, and the other rejoicing that he had discovered facts unrecognized by his brother. Occasionally this state of affairs brought about a ludicrous happening, as for example, when a physician for the plaintiff had testified that the patient's pupils were equal and normal and that there was no difference in vision in the two eyes, and the more observing physician for the defense called the attention of the jury to the fact that the patient had one glass eye, or, as in another instance, when a physician for the defense testified to the perfect neurological conditions found and the physician for the plaintiff demonstrated a serious neurological trouble, and quietly testified that the other physician had not removed a bit of clothing from the patient during his examination. It seemed to me then, as now that this state of affairs was almost unendurable, and, with the cooperation of a group of physicians, I originated, so far as Northern Essex was concerned, the method which is, according to my knowledge, generally adopted in this vicinity at least, by which two physicians meet on practically the same basis as they would meet in a consultation, agreeing on all questions of fact, such as the varying lengths of legs or arms, the absence or presence of cardiac or renal complications etc., and discuss freely the prognosis as to end result and the period of disability. In respect to these two latter matters, there may be an honest difference of opinion, but, before the trial, each knows all the facts in the case and the opinion of the other. While this method was for a time strongly opposed by many attorneys, it has now been accepted by the majority of them, and certainly by all of the better class. At first we were told by some prominent trial lawyers "I will never permit you to consult in that manner with the physician on the other side. I employ you to give me the facts in the case and your opinion. For this I pay you, and I expect you to disclose none of it to anyone else, by doing otherwise you might upset my whole case." The physicians whose opinions were of any value refused to be dominated and, after the method described had been in use for several years, the attorneys agreed that, even from their point of view the plan had been of benefit to all concerned. The success of this method of handling cases is pertinent to the question we have under consideration only as an illustration of what physicians can accomplish by their own initiative.

The so called Briggs law, bringing about impartial examinations and testimony in murder cases has the same pertinency. Its value is shown by the fact stated by Dr Briggs in this hall last year that in only two cases had counsel for one side or the other refused to accept the findings of the impartial report, and in these

two the jury had accepted the impartial findings

If there is to be any relief from the intolerable situation which at present exists in reference to malpractice suits, the initiative will have to come from the medical profession and the plan worked out will have to have the endorsement of the better part of the legal profession. Unless it receives this endorsement it would be difficult to secure an act of the Legislature owing to the large number of attorneys who are sent to that body.

In any method of procedure one thing must be kept clearly in mind. Nothing can be instituted that would take away from the individual his inherent constitutional rights to a trial by jury. This is recognized in the Briggs law and in the procedure in certain cases in equity which are now sent to a Master for a report. Theoretically at least, this Master is supposed to have special qualifications to fit him for the particular type of case which he will hear.

If a law was enacted by which the Judge of a court could refer to a Master, who was a physician, a case of malpractice for a hearing, the report of the latter might well be directed to cover only certain features of the case more particularly the first two at least of the following:

1 What is the end result in this case?

2 Were the acts performed by the defendant and the procedure followed those that are established as proper and such as are in use by physicians properly trained and such as would be in general use in the locality where the physician practiced?

3 Is the end result attributable to the use of improper procedure—this to include action or lack of action?

I concede that there might be some force in an argument against including the third of these questions in the matters sent to a Master on the ground that this is a question particularly for a jury to decide, but after all this method simply adds to the evidence which the jury will consider an impartial report to aid them in coming to their decision. By this plan I believe the constitutional rights of the individual are safeguarded and at the same time the honest and qualified practitioner is to some degree protected against the unscrupulous individual and against the attorney of low moral calibre.

Another argument against this plan also has some degree of plausibility and that is that it would increase the expenses of the county. This may possibly be true, or, in practice, it might be found that the report of the Master followed by a conference in chambers of the counsel for both sides with the Judge might result in the removal from the docket by settlement or withdrawal of a sufficient number of cases to lessen rather than increase the county expense.

There is another plan which, if enacted into law, could not be charged with materially increasing the expense to the county, that is, in cases where malpractice was charged, the court should appoint a physician, properly qualified in respect to the matter under dispute, to be present at the trial, and, at its close, to testify as an impartial witness so appointed in regard to the questions which I have specifically indicated, or at least to questions one and two, he being subject to examination by either or both of the Counsel in the case.

The subject that I have been discussing is always of importance but is of particular significance at the present time as is shown by the fact that one prominent attorney in this State has at present an almost unbelievable number of suits to defend which have been entered against the physicians of one county alone, and he has recently informed me that, in almost all of these cases, the physicians who have been sued are men well-trained, experienced and standing high in professional reputation. To me it is clear that it is our duty on the one hand to protect the person injured by culpable malpractice, and, on the other hand, to protect the qualified physician against the ignorant or unscrupulous individual guided and advised by an ill-informed or unscrupulous attorney.

I can see nothing to be accomplished by this matter being taken up by a small group of the medical profession or by those in one district alone. In my opinion it should be taken up by the Officers of the Massachusetts Medical Society and, with the advice of the Council, a committee of outstanding men should be selected, and an attempt made to secure a study of the subject in conjunction with a similar committee to be appointed by the Massachusetts Bar Association. The recommendation of the joint committee should be referred back to the two societies and, if by them approved, be sent to the Legislature for the enactment of such an Act as is recommended.

SPREAD OF ANTERIOR POLIOMYELITIS

Dr Leroy W Hubbard, director of extension work for the Warm Springs Foundation, indicates in a recent survey that infantile paralysis follows the route of the country's railroad tracks. Travel by automobile, he believes, has also helped to increase

the number of victims of the disease in the United States, now more than 200,000.

Owing to the lack of facilities for aftercare in many small communities, 70 per cent of the funds raised in the President's Birthday Ball this year will remain in the localities where they originate, the remainder going to the Warm Springs Foundation.

CASE 22031

PRESENTATION OF CASE

The patient, a sixty-two year old native widow, was first seen in the Outpatient Department approximately one year and a half before admission. At that time she stated that she had been spitting up blood every day and night for the past six months and two weeks before had coughed up about half a cup of partly clotted blood with very little effort. She occasionally had slight dyspnea on exertion and some ankle edema for the past year. Three months before this visit she had an attack of diarrhea, but her stools appeared normal. Examination at that time was negative except for a systolic apical murmur transmitted to the axilla. The left border of dullness was in the fifth space one to two centimeters beyond the midclavicular line. She was seen in the Pulmonary Clinic ten days later. The lung fields were found to be clear. She was not seen again until September, four months later when she complained of increasing dyspnea, ankle edema and continued blood streaked sputum. Her face was flushed. The lips were cyanotic. The cervical veins were distended. There were a few moist râles at the bases. The blood pressure was 170/95. The heart was enlarged the enlargement being greatest across the base. The first sound was snapping with a questionable diastolic and presystolic rumble. The abdomen was protuberant. The liver was felt one finger breadth below the costal margin. There was a questionable small amount of ascites and slight pitting edema of the extremities. X-ray showed that the diaphragm moved well with respiration. The hilus shadows were increased on both sides and the larger lung markings were prominent, particularly toward the base.

Up until eight days before her admission to the house she had continued to spit up small amounts of blood. At that time she went to bed quite fatigued and was unable to sleep. She became nauseated and vomited two cupfuls of blood. She felt pretty certain that the blood was not congealed up but vomited. It was clotted slightly and not frothy. Nausea was a constant symptom before and after this episode.

At five p.m. the following day she gagged and suddenly tasted something salty in her mouth. This turned out to be about two cupfuls of clotted blood. She did not cough with the appearance of this blood. For the next few days she ate practically nothing but did drink some water. The latter seemed to irritate her stomach and produced more nausea and epigastric distress. She had a third similar attack the following day, but this was associated with a more severe abdominal pain. She thought she was dying and could not get enough air. She was very pale and felt faint and dizzy. The "stomach pain" was steady, gnawing, and apparently just to the left of the epigastrium. She had complete loss of appetite. On the day before admission for the first time she seriously attempted to eat and was able to keep down some beef broth and lamb stew. Her bowel movements had been black and watery for the four days following the first hemorrhage but had not been so before that time. During the week before admission she had attacks of fainting, weakness and dizziness, as well as marked dyspnea.

There was no family history of tuberculosis, insanity or cancer.

She had been married twice. Her first husband died in 1907 of cancer of the stomach at the age of forty-seven. In 1912 she married a drunkard who drank all kinds of liquor. She had one child by her first marriage who was living and well. During this first marriage she had a large number of miscarriages occurring usually at about four months.

Except for an occasional glass of beer she drank no alcohol.

At the age of twelve she had her first attack of rheumatic fever. This recurred the following two winters. She also had pleurisy as a child. Five years before admission she had a hemorrhoidectomy at a local hospital and while there was told that she had a tumor probably in her bowel. Three years before admission she had an attack of marked jaundice without pain or indigestion. This attack lasted two or three months and was followed by what she called pneumonia. She denied venereal disease.

Physical examination showed a senile undernourished woman with mild pallor of the skin and mucous membranes. The heart was enlarged to the right and left. There was a heaving impulse over the precordium and a blowing harsh presystolic and short systolic murmur best heard just inside the apex impulse. P₂ was loud. There was a slight thrill over the apex. The blood pressure was 160/70. In the sitting position an epigastric mass descended with respiration. Another small mass was felt under the left costal border. Both of these masses were tender. The edge of the right lobe of the liver was palpable with inspiration.

Examination of the urine was negative except for an occasional white blood cell. The

blood showed a red count of 3,300,000, with a hemoglobin of 40 per cent. The white count was 3,750, with 72 per cent polymorphonuclears. There was some achromia and chromatophilia. The platelets appeared diminished in number. Three stools were guaiac negative. Both Hinton and Wassermann tests were negative. An electrocardiogram showed normal rate, 75, with diphasic T_1 and T_2 and low T_3 , a moderate left axis deviation, and early intraventricular block. An x-ray examination showed a grossly enlarged heart in all diameters. There was marked prominence in the region of the pulmonary conus without prominence of the hilus shadows. There was a small diaphragmatic hernia.

During her stay the liver and spleen were easily palpable. There was no definite evidence of ascites, although one examiner believed that there was. She was discharged ten days after admission.

Second Admission, ten days later

She remained in bed all of the first week after discharge but thereafter was up and around, although she did not feel too well. One week before this admission after eating some lettuce and potatoes she coughed up a cupful of bright red blood and had a bowel movement consisting mostly of dark red blood. Three days later she again vomited a cupful of blood and again had two or three dark bowel movements. She continued to have the latter up until admission. The day before admission she raised a small amount of bright blood. She continued to have an irritating cough.

Physical examination was the same as on her previous admission, except that there were definite signs of ascites at this time. The blood pressure was 170/80. The spleen was ballotable two or three fingers down. The liver, however, was not definitely felt.

Examination of the blood showed a red cell count of 2,020,000, with a hemoglobin of 40 per cent. The white cell count was 6,200, 78 per cent polymorphonuclears. A guaiac test was positive.

The day after admission she was given 200 cubic centimeters of citrated blood and on the third day lapsed into coma and died.

DIFFERENTIAL DIAGNOSIS

DR. CHARLES L. SHORT. To obtain a clearer conception of the sequence of events in this case it is necessary to combine the histories taken in the Outpatient Department and the house, since in the former some essential details are lacking. The first significant happenings in the medical history of this sixty-two year old woman were three attacks of rheumatic fever in successive years from the age of twelve on. These, together with an attack of marked jaundice three years before admission, are of aid in determin-

ing the etiology of her subsequent presenting symptoms. As far as I can judge, the "tumor probably in her bowel", of which she was informed at another hospital five years before admission here, does not manifest itself later, so that I am forced to pass over this bit of information. We come then to the six months episode of blood spitting, starting two years before admission, culminating in her visit to the Outpatient clinic. At the same time she had had mild dyspnea and edema, suggesting early cardiac failure. The examination at this visit showed probable cardiac enlargement, a systolic murmur at the apex transmitted to the axilla, and clear lung fields by x-ray. When seen four months later there was frank congestive failure, with cyanosis, distention of the cervical veins, basal râles, edema of the extremities, and increase in hilus shadows and larger lung markings in the chest plate. In addition, we now have a "questionable diastolic and presystolic rumble". The picture thus far is that of heart disease, probably rheumatic in origin with mitral stenosis, resulting in pulmonary congestion and hemoptysis. Do we need to look farther for explanation of her hemoptyses? Bronchiectasis, especially of the left lower lobe, ulceration or polyp of a bronchus, early malignant or benign bronchial newgrowth—any one of these might result in blood spitting and yet present no x-ray findings. During the remaining sixteen months of her life no corroboration of any of these diagnoses is obtained, although further x-rays of her chest were taken. I should be willing then to blame her hemoptyses on one of the common causes—mitral stenosis.

During the next year we have no description of this patient's clinical course except the statement that she "continued to spit up small amounts of blood". Eight days before her admission to the house a serious and alarming train of symptoms appeared: the vomiting of blood, nausea and epigastric distress, and black stools, all interspersed with attacks of faintness and dyspnea. Examination at this admission showed pallor, generalized cardiac enlargement, a presystolic murmur and epigastric masses. She had a hypochromic anemia with a low white count. Electrocardiogram showed evidence of coronary disease. By x-ray there was a grossly enlarged heart, with a prominence in the pulmonary conus, suggesting our previous probable diagnosis of mitral stenosis. The epigastric masses apparently resolved themselves into spleen and liver (the left lobe of which is often mistaken for an epigastric tumor). At this time there was a questionable ascites. During her brief stay at home after discharge she again vomited blood and passed bloody and dark stools. On return to the hospital there was definite ascites, the spleen but not the liver was palpable, and her anemia had increased. On

the third day "she lapsed into coma and died", about three weeks after she began to vomit blood.

In considering the differential diagnosis in this patient, let us first discuss the cardiac lesion. In favor of mitral stenosis are the rheumatic history, the shape of the heart by x ray and the presence of compatible murmurs. It would be more satisfactory to have a constant characteristic description of the typical murmurs, but we know that the murmur is often variable with this lesion and may appear only under certain conditions. We are told that at least one out of five individuals with mitral stenosis lives past the fifth decade and Levine has described the association of hypertension with mitral stenosis in later life. I see no reason to account for her signs and symptoms on calcareous disease of the aortic valve although she may show some calcification in this region at autopsy. The electrocardiographic findings indicate some degree of coronary arteriosclerosis, with the left axis deviation accounted for by her hypertension. I believe, then, that the evidence points toward rheumatic endocarditis with mitral stenosis as the basic cardiac lesion and I should thus account for her hemoptysis.

We next must explain her vomiting of blood, enlargement of the liver and spleen and ascites. First, did the blood actually come from a gastrointestinal lesion? Did she swallow blood brought up from the lungs, only to vomit it up again? Such a thing is possible and such cases have been recorded but in this patient I believe that we must assume that the bleeding was actually from the gastrointestinal tract. Secondly can the whole picture be accounted for by her heart failure? The enlarged liver and spleen and ascites of course may be due to passive congestion, and also, but rarely, bleeding from the gastrointestinal tract. The so-called "cardiac cirrhosis" is described and occupies a regular position in the textbooks. I think that Dr. Mallory will agree, however, that heart failure is only a factor in the production of a true cirrhosis. The negative urinary findings again are against congestion as the important underlying condition. I should hesitate then to explain the gastrointestinal bleeding as due either to simple congestion or to varices secondary to a "cardiac cirrhosis."

Next, a lesion of the gastrointestinal tract such as tumor, ulcer, or gastritis may have been present, but there are no positive findings leading to this assumption. We know that occult bleeding and even hematemesis may occur with a diaphragmatic hernia, which was demonstrated by x ray. I can leave this last only as a possibility. The previous attack of jaundice, lasting two or three months, points to liver damage more severe than from the ordinary infectious jaundice. The jaundice may have been

due to a pulmonary infarct but seems of too long duration. At any rate, as Resnick and Keefor have demonstrated, the mechanism of jaundice in such cases is from liver damage due to anoxemia. With the history of this episode I am drawn to consider primary hepatic cirrhosis as the probable cause of her gastrointestinal bleeding, as well as the ascites and splenomegaly. The low white counts are compatible with liver disease. Of course, an examination of her esophagus with barium for the presence of varices would have been of great interest and perhaps diagnostic. It would be hazardous to attempt to determine the actual sort of cirrhosis present, but the nodular type, or so-called toxic cirrhosis following subacute atrophy, is a distinct possibility.

You will remember that her downhill course was extraordinarily rapid, with only three weeks between the first hematemesis and her death. Acute decompensation of the liver is seen of course, in cirrhosis and this is the more likely explanation. However, the acuteness of the condition with fresh blood passed by rectum suggests the possibility of portal thrombosis, which is usually secondary to cirrhosis, often of the toxic type. This is a rare condition and difficult to diagnose in life, but should be thought of when the ordinary course of cirrhosis is so accelerated.

To sum up then, I believe that this patient had chronic rheumatic valvular disease, with mitral stenosis and congestive failure. The last may have been an additive factor in the production of cirrhosis of the liver, perhaps toxic in type. The patient died from gastrointestinal bleeding secondary to the hepatic cirrhosis, with portal thrombosis a distinct possibility.

CLINICAL DIAGNOSES

Portal cirrhosis with ascites.
Rheumatic heart disease.
Mitral stenosis and regurgitation.
Esophageal varices.

DR. CHARLES L. SHOLT'S DIAGNOSES

Mitral stenosis.
Coronary sclerosis.
Hypertension.
Cirrhosis of the liver, ? toxic.
Portal thrombosis?

ANATOMIC DIAGNOSES

Rheumatic heart disease.
Endocarditis, chronic rheumatic with mitral stenosis.
Cardiac hypertrophy.
Cirrhosis of the liver, toxic.
Esophageal varices with erosion.
Splenomegaly.
Ascites.
Hydrothorax bilateral.
Pulmonary edema.

Arteriosclerosis Coronary and aortic moderate to marked, renal slight
Leiomyoma uteri

PATHOLOGIC DISCUSSION

DR TRACY B MALLORY The findings at autopsy were almost exactly what Dr Short has predicted. The heart was considerably dilated and moderately hypertrophied, weighing 400 grams. The mitral valve showed a marked degree of stenosis, the lumen measuring only 1.5 by 0.5 centimeters. The aortic valve was uninvolved. The coronary arteries showed a moderate degree of atheroma with slight calcification and distinct narrowing of the descending branch of the left one. The kidneys showed a mild grade of nephrosclerosis consistent with the degree of hypertension which had been found. The liver, in spite of having been readily palpable, was distinctly atrophic, weighing only 1150 grams. Its surface was coarsely nodular rather than granular, and the nodules varied from seven-tenths of a centimeter to three centimeters in diameter. They were separated from each other by extensive grayish patches of fibrous tissue, which on microscopic examination showed the closely packed branching bile ducts which originally supplied many lobules but now failed to connect with any liver cells. The picture is entirely typical of the postacute yellow atrophy type of cirrhosis. The esophagus showed in its lower third many enlarged tortuous mucosal veins, overlying one of which was an erosion, 2 millimeters in diameter, in which lay a small thrombus. The lungs were negative except for chronic passive congestion. The spleen was considerably enlarged, weighing 550 grams, and showed the early fibrotic changes which one expects in a case of portal obstruction whether the obstruction is in the liver in the form of cirrhosis or in the splenic or portal veins in the form of thrombosis. The leukopenia is, in my estimation, directly dependent on this type of splenic enlargement. The splenic and portal veins were, as a matter of fact, free from thrombi, but Dr Short was not taking a very "long chance" in gambling upon their presence. The only other finding which may bear upon the clinical history was the presence of a fibroid, 3 centimeters in diameter, on the anterior surface of the uterus. It is not impossible at any rate that this was the tumor felt in the abdomen at her entry to the other hospital.

CASE 22032

PRESENTATION OF CASE

First Admission A thirteen year old American schoolgirl entered complaining of swelling of the feet, face and eyes of four weeks' duration.

Six months before admission she began to have dull, severe, frontal and occipital headaches every three or four days. They gradually became more frequent and were severe enough to keep her from school. One month before entry she noticed pain in the calves of her legs while walking. She also noticed mild shortness of breath upon exertion. Two and a half weeks before entry she fell into a pond and the following day noticed that her feet were swollen. The next day there was swelling of the hands and face. She was put to bed and given a milk diet and some red pills for her urine. She had some loss of appetite but no nausea, vomiting or red or smoky urine. During the week before entry the swelling had gradually disappeared leaving only a slight puffiness of the eyes.

Her family history is noncontributory.

There was no history of chorea, rheumatism, pneumonia, scarlet fever or tonsillitis.

Physical examination showed a well-developed and nourished, slightly pale girl with very slight puffiness under the eyes. The fundi were normal except for a few black spots near the macula of the left eye. The teeth were carious. The tonsils were moderately enlarged but not inflamed. The lungs were clear except for a small area at the left base where there were flatness, diminished breath sounds, tactile fremitus and spoken voice. The heart was not enlarged. The first sound was not very clear and was followed by a blowing systolic murmur which was transmitted into the axilla. The blood pressure was 130/78.

The temperature was 99°, the pulse 80. The respirations were 20.

Examination of the urine showed a specific gravity of 1.015 to 1.022, a trace to a large trace of albumin and a sediment which contained 15 to 20 white blood cells, 3 to 5 red blood cells, and numerous finely granular and hyaline casts. The red blood cell count was 4,410,000, with a hemoglobin of 75 per cent. The white cell count was 9,400, 73 per cent polymorphonuclears. The stools were negative. A Hinton test was negative. The nonprotein nitrogen of the blood was 27 milligrams, the carbon dioxide combining power 48.6 volumes per cent. The chlorides were 614 milligrams per cent, the serum protein 3.9 per cent and the cholesterol 298 milligrams per cent. The phenolsulphonephthalein test gave 40 per cent excretion in two hours. A urea clearance test showed a maximum clearance of 27 cubic centimeters of blood with 36 per cent average normal function. Another test showed a maximum clearance of 34 cubic centimeters of blood with an average normal function of 45 per cent. A urine concentration test showed a swing from 1.005 to 1.015 to 1.022.

X-ray examination of the chest showed ho-

mogeneous dullness obliterating the left costophrenic angle.

She continued to have red and white blood cells and casts in the urine. The signs in her chest cleared up and she was discharged improved three weeks after admission.

Second Admission, four months later

For one month after discharge she felt quite well. At this time she developed a sore throat with pain, swelling and cervical adenopathy. Following this sore throat the edema around her eyes became more marked and she soon complained of quite severe frontal headaches which were present almost every day. Two months before entry her abdomen began to swell and continued to do so until admission. Two weeks before entry she had a slight cold which increased the swelling about her eyes. There had been, however, no edema of the legs or ankles. There was no hematuria or polyuria. Her water intake had been very low not more than two glasses a day. Her appetite had been good and her bowels regular. There was no dyspnea or palpitation.

On physical examination there was marked puffiness under the eyes. The skin and mucous membranes were pale and there were numerous carious teeth. The tonsils were enlarged and infected. There was limited expansion of the left chest and except for a small area at the apex of the left chest there was dullness to flatness, diminished to absent tactile fremitus and breath sounds. Similar findings were present at the right base posteriorly. The heart was displaced to the right. The abdomen was tense, doughy and showed a marked fluid wave. The blood pressure was 140/110. There was edema of the back, but none of the extremities. The fundi were normal.

The temperature was 98.6° the pulse 98. The respirations were 20.

The specific gravity of the urine was 1.017 to 1.026. There was a large trace of albumin. The sediment was loaded with white blood cells, a few red blood cells and numerous hyaline and granular casts. The red blood cell count was 4,050,000 with a hemoglobin of 60 per cent. The white cell count was 13,000, 85 per cent polymorphonuclears. The nonprotein nitrogen of the blood was 35 milligrams, the serum protein 4.52, the cholesterol 347 milligrams per cent. A phenolsulphonphthalein test gave 50 per cent excretion, 15 per cent of which occurred in the first fifteen minutes.

She responded well to salyrgan, losing nineteen pounds in about three weeks. At the end of that period a tonsillectomy and adenoidectomy were performed. Several infected teeth were removed. Thirteen hundred cubic centimeters of serous fluid with a specific gravity of 1.009 was removed from her left pleural cavity on

one occasion and 1250 cubic centimeters one week later.

Final Admission, three years later

Following her second discharge from the hospital the patient remained at home and was fairly well. She led a fairly normal life although she did no work and had no strenuous exercise. She was on a high protein diet but was later changed to a low protein, low salt diet and finally to a normal diet with salt restricted. She continued to have throbbing frontal headaches during the three months before admission. She had been followed in the Out Patient Department where it was found that her renal function was steadily diminishing, her blood pressure rising, and marked eye ground changes were noted. Her parents thought that she had been going downhill steadily seemed less bright and active, complained of more headache and vomited on several occasions. During the month before admission she had nocturia one or two times. Five days before entry while sitting in a chair she suddenly became rigid and stiff. The right arm and leg and right side of the face twitched. This attack lasted five minutes. The patient was unaware of the attack but complained of severe headache following it and vomited twice. There was no paralysis or weakness. Since then she had been constantly in bed and complained of constant dull frontal headaches and blurring of vision. Prior to this episode she had been able to read without difficulty. Since then she had twitchings in various muscles.

Physical examination showed a fairly well developed and nourished, pasty looking girl with pale skin and mucous membranes. She had a blank stare and was unable to recognize any one. Both fundi showed obliterated discs with marked choking as well as many irregular, flame shaped recent hemorrhages and patches of irregular yellowish exudate in both retinæ. Small portions of the retinal arteries were tortuous and of irregular caliber. There was separation of the lower portion of the right retina. The heart was markedly enlarged to the left. The sounds were loud and snapping with a split first sound at the apex and gallop rhythm over the sternal region at the level of the third rib. The blood pressure was 194/130. There were occasional coarse muscular twitchings in the extremities and trunk. The right tendon jerks were more active than the left.

The temperature was 99°, the pulse 90. The respirations were 18.

The urine was red small in quantity, had a specific gravity of 1.010 to 1.014, and contained a large trace of albumin and large numbers of white blood cells and red blood cells. The red blood cell count was 2,800,000 with a hemoglobin of 45 per cent. The white cell count was 6,800, 67 per cent polymorphonuclears. The nonprotein nitrogen of the blood was 125 ml

ligrams The carbon dioxide combining power was 53.7 volumes per cent, the serum protein 6.5 per cent, the serum calcium 7.9 milligrams, the serum phosphorus 9.64 milligrams per cent and the cholesterol 250 milligrams. Two lumbar punctures were done which relieved her headaches temporarily. The fluid was under greatly increased pressure (500 millimeters). She very rapidly failed, developed rhonchi in the upper chest and moist râles at the bases and died one week after entry.

DIFFERENTIAL DIAGNOSIS

DR EARLE M. CHAPMAN To sum up, we have a thirteen year old girl who first complained of swelling of the feet and face and dyspnea on exertion. Physical examination showed her to be pale and edematous, with the chest signs, substantiated by x-ray, of pleural effusion. The blood pressure was slightly elevated. Laboratory examination at first entry showed gross albuminuria with only a few red blood cells and casts in the urine, a slightly lowered CO_2 combining power (mild acidosis), an elevated blood cholesterol and a lowered serum protein. The total output of phenolsulphonephthalein was decreased and the urea clearance was markedly reduced. The normal range for the maximum clearance is 85 to 132 per cent of average normal function. Van Slyke has found that edema disappears and death from uremia usually follows when the clearance goes below 20 per cent. As in most forms of acute Bright's disease the concentration of urine was surprisingly good.

The diagnosis seems clearly to be one of Bright's disease as the cause of edema and albuminuria. Of course, one must consider failure of the heart or liver as well as the kidneys as these organs are the most frequent sites of disease in the syndrome of edema and albuminuria. However, I believe we can accept a diagnosis of nephrosis or the nephrotic stage of acute Bright's disease.

Aggravation of her disease followed an acute infection, tonsillitis and cervical adenitis, and four months later she returned with marked edema, pleural effusion, ascites and a further elevation of the blood pressure. Mild anemia was now present and the blood cholesterol was even higher. The curve of phenolsulphonephthalein excretion was depressed, although the total two hour output was 50 per cent. An attempt was made to remove the foci of infection in the teeth and tonsils. Unfortunately bacteriologic studies of these were not recorded. We know that in acute hemorrhagic nephritis hemolytic streptococci have been cultured from foci in about 80 per cent of the cases.

Nephrosis, like hemorrhagic nephritis, is associated with infection, and the presence of red and white blood cells and casts in the urine sug-

gests inflammatory changes in the glomerular capillaries. It has been our experience here as well as in other hospitals that as we have followed a few of the young adults through months to years of this illness that they may gradually change from the nephrotic picture to one of chronic hemorrhagic (glomerular) nephritis. Coincident with this change come the appearance of marked anemia, hypertension with progressive changes in the systemic arterioles and finally death in uremia.

It seems that this girl progressed steadily along this course. Finally, with increased glomerular damage nitrogen retention appeared. The uremic twitchings are explained by the low blood calcium which has fallen in response to the rise in phosphorus. Even slightly damaged kidneys are unable to excrete phosphorus in normal amounts and if it was at all practical a phosphorus clearance test would probably be the most delicate test of kidney function. The headaches and mental torpor were due in part to hypertensive encephalopathy. Treatment of this by lumbar puncture in acute nephritis may be a life-saving procedure but here we could expect only temporary relief.

Stubborn edema without anemia, hematuria, hypertension or nitrogen retention has been taught as a requisite for the nephrotic syndrome but strict adherence to this formula is not necessary. It has been overlooked that four of the five cases in Munk's early description of nephrosis had microscopic hematuria, that in three a low hemoglobin was recorded, and in none was the blood pressure noted. Nephrosis is also characterized by massive proteinuria, of which the globulin content is low, and by a reduction such as we see here in the serum protein with a relatively high globulin content. In addition, there is some change in fat metabolism reflected by an elevation in blood cholesterol. Adequate explanations for all these changes are lacking.

Critical chemical analyses have given us a better understanding of the changes produced in nephrosis but the problem of finding the agent provoking these changes still remains open. Stimulation and hope are to be found in the recent work of Blackman in Baltimore who calls attention to the possible rôle of the pneumococcus. This idea is not original but he has gone a step farther and produced nephrosis in rabbits with a pneumococcus toxin and in ten autopsied children he found that an overwhelming pneumococcus infection was the terminal event. In four of these a type II organism was recovered, which is extraordinarily high when one considers that less than 8 per cent of all pneumonias in childhood are due to the type II. So far as I know immunologic studies in nephrosis have not been done.

In conclusion, I believe this girl had nephrosis and that her course ending in uremia is

good evidence that we can no longer look on nephrosis as a separate metabolic disease but only as a little understood stage in hemorrhagic nephritis. In addition to lipoid tubular changes we may expect extensive damage to the glomerular capillaries.

CLINICAL DIAGNOSES

Chronic glomerular nephritis
Hypertensive encephalopathy

DR. EARLE M. CHAPMAN'S DIAGNOSIS

Chronic hemorrhagic nephritis, with nephrotic syndrome at onset.

ANATOMIC DIAGNOSES

Nephritis, glomerular, chronic
Cardiac hypertrophy and dilatation.
Pulmonary edema
Bronchopneumonia, early
Arteriosclerosis, cerebral, type undetermined
Follicular cyst of ovary, right.

PATHOLOGIC DISCUSSION

DR. TRACY B. MALLORY The recognition of two distinct types of Bright's disease variously named, hemorrhagic and edematous by some nephritic and nephrotic by others, is now of over twenty years' standing. Yet the relationship of the two types, whether they are different diseases of different etiologies or simply two types of the same disease is still a subject of lively and occasionally bitter controversy. The root of the difficulty lies probably in the apparent discrepancies between functional perversion and anatomic abnormality which prevent the clinician and the pathologist from agreeing upon any classification. Certain predictions as to the anatomic changes can be made with a fair percentage of success in a considerable group of cases but in any single case one's arrow may fly far from the mark. It is generally safe, for instance, to predict that

with marked edema, albuminuria, hypoproteinemia and hypercholesterinemia the glomeruli will show inconspicuous changes only and the tubules will show marked degenerative changes. Yet exactly the same functional derangements occur quite regularly in amyloid disease where the tubular changes are inconspicuous and the glomerular lesions are predominant. Occasionally, moreover, a histologically typical glomerulonephritis without noticeable tubular lesions will be associated with the classical nephrotic syndrome. Experience shows that the great majority of "nephroses" are not quite true to the theoretical type either from the clinical or the anatomical point of view. Usually a few red cells will be found, or the blood pressure is a little elevated, or there is a little nitrogen retention. The anatomic counterpart is, of course, the finding of definite inflammatory changes in the glomerular tufts and it is always safe to assume that histologic studies will show more rather than less glomerulitis than the functional studies indicate. Another very safe assumption is that nearly every case of Bright's disease will prove at autopsy to be more chronic than the story seems to indicate. Both of these assumptions are borne out in today's case. The kidneys show a marked glomerulonephritis which has already passed into the chronic stage characterized by complete sclerosis of numerous glomeruli with extensive secondary atrophy of many tubules and compensatory dilatation of the remaining ones. A few glomeruli, however, still show active inflammatory lesions. Grossly the pair of kidneys weighed 225 grams and showed pale grayish granular surfaces. The heart was markedly dilated and considerably hypertrophied, weighing 340 grams. There was a very slight obviously terminal bronchopneumonia. The only other finding of significance was a considerable degree of arteriolar sclerosis, unusually marked in this patient in the brain. There were however, no demonstrable secondary changes in nerve cells or fibers or in the glia.

The Massachusetts Medical Society

THE ANNUAL MEETING

As has been announced, the One Hundred and Fifty-Fifth Annual Meeting of the Society will be held in Springfield June 8, 9 and 10, 1936. Some of the special features have been referred to in an editorial published in this *Journal* on January 2, 1936. Not only does the excellent work of the Committee of Arrangements in providing a worth while program of scientific papers and exhibits deserve the support of the Fellows by their attendance, but the importance of the business meetings demands their intelligent participation.

The business of the Society has become increasingly complex and there is the greatest need for coordinated action based upon thorough appreciation of all factors if the Society is to render the best service to its Fellows and advance the interests of the profession of medicine. The Council will hold its annual meeting on Tuesday, June 9, will hear the reports of its officers and standing committees and will act upon such recommendations as may come before

it. The Councilors are the chosen representatives of the district societies and each should be in such close touch with the Fellows in his district as to enable him to bring to the Council representative opinion. Since each district will select its Councilors prior to the annual meeting, every effort should be made to choose those who will work for the common good.

The Annual Meeting of the Society will be held at noon on Wednesday, June 10, and, since all Fellows in good standing are eligible to attend, it is hoped that there will be a large number present.

The presidents and secretaries of the district societies are urged to do all in their power to encourage their members to attend, particularly those who have been more recently admitted to Fellowship.

AN AMENDMENT TO THE LAW PROVIDING FOR THE REGISTRATION OF PHYSICIANS

For more than forty years the Board of Registration in Medicine has been operating under a law which was defective in its original form, and has not been sufficiently modified since 1894 to enable the Board to perform its function in protecting the public as well as can the Boards in every other state in the Union. The legislatures of all the other states have adopted certain effective requirements relating to medical education or have given authority to boards of medical registration to determine acceptable minimum standards for medical schools.

In Massachusetts the applicant for registration as a practitioner of medicine is required only to show that he has had a premedical education equivalent to that necessary for graduation from high school, and a medical degree from a chartered school which requires of its students attendance on courses covering four years of thirty-two weeks in each year. He must also be free from suspicion as to moral character. If these requirements are met, the Board must accept him for examination. These requirements can be met by a person who has had a medical education which does not meet generally accepted standards and a considerable number of physicians with this kind of training are now practicing in Massachusetts.

The Massachusetts Board of Registration in Medicine has recommended to the Legislature that amendments be made to the existing law which will give to the Board power to determine whether a given medical school from which an applicant has graduated is worthy of recognition. The text of this proposed amendment was published in the *Journal* of November 7, 1935 on page 938. By reason of the limited power of the Massachusetts Board reciprocal relations with other states respecting the registration of physicians have been denied. This

is humiliating so far as the state is concerned and annoying to practitioners who may wish to settle elsewhere after having been licensed by our board.

Where does the blame lie for this predicament? Certainly not with the Board for it has consistently and persistently tried to have the General Court correct this unfortunate situation. It must lie with the more intelligent part of our people who have been indifferent and disinclined to educate the general electorate concerning the importance of having well trained doctors available in cases of illness. The medical profession may ask itself in all honesty whether it has contributed its full measure of influence to an adequate educational campaign throughout the state.

Massachusetts was one of the last of the states to adopt statutory regulation of the practice of medicine and has the reputation of being the weakest link in the chain forged to protect the people against disease. The original statute was enacted in response to a petition by representatives of the Massachusetts Medical Society among whom were Dr. Reginald Heber Fitz, Dr. George Washington Gay and Dr. Edward Bayard Harvey. Let us honor their memory by following their example.

The hearing on the proposed amendment House Bill 34 will be held on January 23 in Room 480, State House, Boston, at 10:30 A.M. before the Legislative Committee on Education. Undoubtedly the opposition will be articulate and fervent, as in the past. In favor of the bill, the Massachusetts Medical Society will make official representation. At the hearing, there will be opportunity for the individual members of the Massachusetts Medical Society who favor the proposed change in the law also to voice their opinion, so that through official and individual representations, the Legislature may be in no doubt as to what the medical profession in Massachusetts wants.

THE GOVERNOR'S ANNUAL MESSAGE

His Excellency the Governor, during a long political career, has been noted for the fidelity with which he has safeguarded and promoted the interests of public health and those who have been working in these interests. No matter what expediency may have dictated in other branches of municipal and state government, the health of the City and of the Commonwealth has not been made the football of politics.

In his annual message to the Legislature, His Excellency again does not neglect this important duty of the Commonwealth to its citizens, making several recommendations which form a considerable part of the total document. First

among these is the recommendation of such additions to existing law as would make possible the inclusion of institutional nurses within the provisions of the Workmen's Compensation Act.

Reorganization of the Department of Labor and Industries is essential, according to Governor Curley, giving over to this department the duties of the Industrial Accident Board. It is the opinion of the Governor that the division of jurisdiction between these two agencies causes much wasteful overlapping of effort and defeats the purpose which should be the primary objective of both—the prevention of industrial accidents and diseases.

His Excellency points out that a mental disease research building was completed at Wrentham in 1931, but that to date no funds have been forthcoming for its equipment. For this purpose \$12,000 is asked of the Legislature. The proper care of mental defectives in general, however, has become a serious problem, our twelve state institutions with a working capacity of 17,671 patients are now caring for 21,023, and speedy enlargement of these institutions to care for 2,000 patients each is urged. New living quarters should also be provided for at least 1,500 employees.

The three state schools under the Department of Mental Diseases are now caring for 5,051 patients with a working capacity of 3,893 and 3,200 applications are on file for patients for whom there are no possible accommodations. These three schools should also be brought up to a 2,000 working capacity apiece, and an extra school should be provided.

The hospital for the criminally insane at Norfolk, the establishment of which was enabled by an act of 1935 but with no funds provided for its building, should be constructed at once and an appropriation of \$1,750,000 is requested for this purpose. This hospital should be under the Department of Mental Diseases rather than under the Department of Correction.

It is further recommended that the old Rutland State Sanatorium be razed and replaced by a modern structure and that both here and at the Pondville Cancer Hospital additional accommodation for employees be provided during the present year. The question of the establishment of an institution for the care and treatment of persons afflicted with social diseases should be studied by a committee to report to the Legislature in 1937.

The annual registration of physicians is recommended in view of the large number of unqualified individuals now practicing in this state and the enactment of legislation is requested making it a criminal offense to practice as a physician without such registration.

The citizens of our Commonwealth will note with interest that His Excellency advocates the

installation of 30-mile-per-hour speed governors on the motor cars of automobile law violators

It must be apparent that these recommendations are in the main worthy ones, if funds are available for putting them into effect, and the Governor is to be congratulated on the forcefulness with which he presents them

INTERRUPTION OF PREGNANCY

There are definite complications which make it unsafe for some patients to proceed in pregnancy The advances in modern medicine are reducing this number materially Nowadays it is unusual to feel that patients have to be aborted because of pernicious vomiting Insulin is making pregnancy safe for many diabetics who ten or fifteen years ago could not safely have a baby There still remain, however, patients suffering from kidney trouble, hypertension, heart trouble, psychopathic disorders, tuberculosis and malignant disease, who really ought not to be allowed to become pregnant, and who, if they do become pregnant, should be aborted If one feels that any pregnant patient for any reason cannot stand the drain of pregnancy without seriously jeopardiz-

Comments and questions by subscribers are solicited and will be discussed by members of the Section.

ing her own life, one must first of all have the best advice in consultation. If a consultant agrees that interruption is indicated, the abortion should be performed as much in the open as possible. The best hospital in one's community is always the best place to perform the operation. Selfishly, the physician should take this into account. He should never leave himself open to any criticism. The private home should never be used for any abortion unless it is absolutely impossible to hospitalize the patient.

It is unwise to attempt to perform an abortion before the pregnancy is six weeks old. If the abortion is done too early, it is possible to get curettings which will give a pathological diagnosis of pregnancy and yet not interfere with the ovum. If this happens, it of course necessitates a second operation at a later period. This means second hospitalization, unnecessary financial loss and added risk. The ideal time to perform any therapeutic abortion is between six and eight weeks. The operation is done readily at one sitting by a thorough curettage unless it is felt that sterilization should be done at the same time. It is almost impossible to curette a uterus quite cleanly that is not already aborting. One gets as much of the products of conception as one can, packs the uterus for twenty-four hours with gauze soaked in iodine and leaves nature to finish the process.

In cases that are beyond three months the emptying of the uterus by curettage is often dangerous. It is dangerous from the standpoint of hemorrhage. It is dangerous from the standpoint of infection. If a patient is between the months of four and seven, either abdominal or vaginal hysterectomy is the method of choice. If sterilization is to be performed, the interruption should be done, of course, by the abdominal route.

The choice of the anesthetic to be used depends upon the complication. It seems wisest in patients of the psychopathic type that a general anesthetic be used. In any case that needs to be interrupted a general anesthetic may be used unless there is some pulmonary complication. Spinal anesthesia is practicable in cardiacs, nephritics, and in those cases suffering from any pulmonary complication.

If a patient has a chronic disease which makes it inadvisable to have one baby the question arises as to whether she should be allowed to have any babies at all, and in consequence many of these cases had best be sterilized at the time the uterus is emptied. If the pregnancy has advanced very far or if the patient's condition is extremely poor, sterilization is best performed by the method described by Bishop of Brooklyn. This consists in merely picking up a loop of each tube in the middle, tying it at the base of the loop with catgut, and excising the loop. The whole performance can be done in not more

than two minutes, and runs no risk of causing pelvic hematomas. If the patient's condition is perfectly satisfactory and one feels that the patient can well stand what added risk there is to hysterectomy, the sterilization and the interruption of the pregnancy may be accomplished by removal of the uterus. If the condition of the patient is extremely critical hysterectomy may carry with it added dangers which simple ligation and excision of a piece of tube do not carry and in this case, in consequence, is contraindicated.

A PRIZE FOR AN APPROVED ESSAY

The attention of interns in Massachusetts hospitals is called to the fact that a prize of \$50.00 has been offered by the Massachusetts Medical Society for the best written and most comprehensive case report submitted by one of their number holding a rotating internship in any Massachusetts hospital which is approved by the American Medical Association for intern training during 1935-1936.

This report is to be typewritten and when completed is to be sealed unsigned, in a plain envelope which in turn is to be placed together with a separate slip bearing the name and address of the contestant, in a larger envelope and sent to

The Massachusetts Medical Society
Committee on Medical Education and Medical Diplomas,

8 Fenway Boston Mass.

The contest this year closes May 1 1936. Reports may be submitted at any time prior to that date.

BOSTON MEDICAL LIBRARY

SIR DOMINIO CORRIGAN 1802-1880

The name of Corrigan calls to mind the observations of the clinician who first focused attention upon the peculiar type of pulse distinguishing certain lesions of the aortic valves. To have done the investigating necessary to establish the relation of faulty closure of these valves to the production of Corrigan's pulse stamped the one who did it as a sufficiently qualified candidate to be admitted, without examination to membership in the Royal College of Surgeons for it is related that when he presented himself for examination the first question asked him was 'Are you the author of the Essay on Patency of the Aortic Valves?' and upon his acknowledgment that he was, no further questions were asked.

Dominic Corrigan was born in Dublin in 1802, the son of John Corrigan a man of ability, a successful farmer and distributor of agricultural implements, in which business he evidently was able to amass a comfortable fortune, for he gave his children excellent educational advantages. Dominic's mother was a talented woman of social prominence. He at

tended a Catholic College at Maynooth where he became well grounded in languages and physical science. His abilities in the latter line were so outstanding that he was frequently called upon to assist the Professor in his classes. The way to medical practice in that period was through apprenticeship to an established practitioner and Dr O'Kelley, who served in that capacity, became so impressed by Corrigan's talents that he urged his father to send him to Edinburgh, which he did. From there he was graduated as a Doctor in 1825, at the age of twenty-three. He returned to Dublin and set himself up in practice. During the period of waiting for his services to be in demand he applied himself diligently to the study of the history of medicine and worked hard in familiarizing himself with the literature of his profession. He elected to do this rather than resort to some of the more usual and somewhat questionable methods of attracting attention to himself, then in common use. Later in life he repeatedly urged his students to follow the same course. His continued interest in educational methods furnished him frequent opportunity to urge his views, perhaps the most noteworthy example of which was in his address on medical education before the Annual Meeting of the British Medical Association, held in Dublin in 1867, where he advocated a higher standard of general and professional education for medical men. He was a forceful speaker and is said to have had few equals in presenting arguments in support of any proposition he was advocating. His faults were largely due to a somewhat unbridled temper which made him unnecessarily caustic in his criticisms, thereby courting opposition that otherwise might not have developed. He successively served the Digges St School, the Peter St School and the Carmichael College besides the Jarvis St Hospital where he first had a service of his own, though of only six beds. It was here, however, that he demonstrated the aortic valvular lesions which made his name well known the world over. It was Trousseau who gave the name "Maladie de Corrigan" to aortic regurgitation. In acknowledgment of his services to education he was made a Baronet in 1866. His most noteworthy papers, aside from the one upon the patency of the aortic valves, were his "Lectures on Fevers", delivered at the House of Industry Hospital, and "Cirrhus of the Lungs". He was interested in fevers and was one of the earliest of the clinicians to differentiate typhoid and typhus. He had unusual opportunities to follow out his interest in fevers when he joined the staff of the Hardwicke Hospital. In 1832 he helped to fight an epidemic of cholera that descended upon Dublin. His experience taught him the importance of pathology in its application to prognosis and treatment. His lectures and clinical demonstrations at the Hospital, held at 8 o'clock

in the morning, were so popular that it was hard to gain admission and all of the courses were equally popular. He was persuaded to stand for election to Parliament where his friends thought his forensic abilities and the soundness of his views upon public matters would ensure his success. He won the election, but the experience did not add much to his distinction and he was not reelected.

He was not a wide reader of current literature, preferring the old classical authors and was especially devoted to Morgagni. His fame as a consultant became so widely spread that he was unable to see all the patients who sought his advice and was often compelled to make his escape from his consulting rooms through a back entrance. Interest in scientific medicine, popularity as a clinical teacher, as well as a consultant in practice, and willingness to respond to innumerable demands upon his time for public-spirited service more than filled his time and took their toll from his health. Gout, from which he suffered for several years, impaired his usefulness and not long before his death, on February 1, 1880, he was the victim of a cerebral hemorrhage and in this way ended the career of one of the most beloved of a small group of Irish physicians who made the Dublin School famous in the mid nineteenth century.

MASSACHUSETTS LEGISLATIVE NOTES

The hearing on House Bill 34, which gives to the Board of Registration in Medicine power of approval of medical schools whose graduates are candidates for examination and also requires two years of collegiate work before admission to medical school will be held on Thursday, January 23, 1936, in Room 480, State House, before the legislative Committee on Education. It is especially important that members of the medical profession be present and express to the Committee on Education their views on this matter, which so deeply concerns the health of the people of Massachusetts.

MISCELLANY

ADDITION TO WEYMOUTH HOSPITAL

An addition to the Weymouth Hospital, built largely through PWA funds, was opened for public inspection on January 11. The new wing houses the maternity ward, with nursery, a diet kitchen, two operating rooms, and the accident, laboratory and X-Ray Departments. With its twenty beds it increases the capacity of the hospital to ninety beds.

COMMUNITY FUND CAMPAIGN

Dr John P Monks, chairman of a large committee of Boston physicians who are forwarding the 1936 Community Fund Campaign announces the following additions to his committee

Vice-Chairman

Dr James A. Halsted

Group Committeemen

Dr Theodore Badger	Dr Albert A. Hornor
Dr Myles Baker	Dr Francis C. Newton
Dr Trygve Gundersen	Dr Earle M. Chapman
Dr Rlohard Stetson	Dr Richard Chnte
Dr William M. Shedden	Dr Sven Gundersen
Dr Lanrence B. Ellis	Dr Charles L. Short
Dr Randolph K. Byers	Dr John Strieder
Dr Edward S. Emery Jr	Dr Thomas V. Urmy
Dr Lewis W. Hill	Dr Richard H. Wallace
Dr Gerald Hoaffel	

The 1936 Community Fund Campaign replacing the "Emergency Campaigns" of former years, is an intensive drive to raise \$3,750,000 between January 26 and February 10 to serve 100 hospitals, health and social agencies in the membership of the Community Federation of Boston.

CONNECTICUT NEWS ITEMS

The engagement was recently announced in Providence, R. I., of Miss Florence Bates Haynes to Dr James Dixon Case, both of that city. Dr Case was formerly a resident of Hartford, Conn. He was graduated from Trinity College and Yale University School of Medicine and served an internship of eighteen months at the Hartford Hospital.

Among the appointments made by Mayor Spellacy of Hartford as he assumed office in December 1935 was that of Dr George E. Cogan to the Board of Health Commissioners. Dr Robert V. Boyce formerly vice president of the board was elected president and Dr Cogan vice president at a meeting on January 2, 1936. It was voted to continue Dr Thomas F. O'Brien as acting health officer of Hartford until March 31, 1936.

APPOINTMENTS AS MEMBERS OF THE HARVARD MEDICAL SCHOOL FACULTY

Appointment of the following as members of the Harvard Medical School Faculty to September 1, 1936 has been approved by the Harvard Corporation

Orville T. Bailey of the Peter Bent Brigham Hospital, Boston A.B. Syracuse 28, M.D. Albany Medical College 32 as Instructor in Pathology

John H. Harrison of the Peter Bent Brigham Hospital Boston S.B. University of Virginia 29 M.D. ibid. 32 as Assistant in Genito-Urinary Surgery

Edward A. Edwards of Brookline Mass., M.D. Tufts 28 as Research Fellow in Anatomy

Marjorie A. Benedict, of Cambridge, Mass., A.B. Mt. Holyoke 31 Ph.D. Massachusetts Institute of

Technology 35 as Research Fellow in Physical Chemistry

Jack Spencer of Boston, Mass., M.D. University of Virginia 31 as Research Fellow in Medicine

Harold O. Wagner of Medford Mass. S.B. Massachusetts Institute of Technology 22 S.M. ibid. 23 M.D. Rush Medical College, Chicago 30 as Research Fellow in Medicine

Robert S. Schwab of St. Louis, Mo. A.B. Harvard 36 M.D. ibid. 31 as Assistant in Neurology and Psychiatry

Edward P. Motley of Boston, Mass. Assistant in Physiology

Marcel L. Berard of Lyon, France B.A. Lyon University 26 He completed the requirements for medical degree at Lyon University in 1934 and is now studying at Harvard Medical School under University of Paris Fellowship / Appointed Research Fellow in Surgery

Alexander C. P. Campbell of Edinburgh, Scotland M.B. and Ch.B. University of Edinburgh 30 now studying at the Harvard Medical School under a Rockefeller Fellowship appointed Research Fellow in Neuropathology October 1, 1935 to September 1, 1936

Marion R. Smith of the Boston City Hospital S.B. Hamilton College 28 M.D. University of Rochester 33 appointed Assistant in Surgery November 1, 1935 to September 1, 1936

Roger S. Mitchell of Glens Falls N. Y. A.B. Harvard 30 M.D. ibid. 34 appointed Assistant in Neurology February 1 to September 1, 1936

John A. Boone, of Harlingen, Texas, M.D. Harvard 33 appointed Research Fellow in Medicine March 1, to September 1, 1936

APPOINTMENT OF DR. KARL V. QUINN

Dr Karl V. Quinn formerly assistant superintendent of the Belchertown State School, has been advanced to take the position of Assistant Commissioner of Mental Diseases in the Massachusetts Department of Mental Diseases.

Dr Quinn was born in 1902 and graduated from Queen's University Faculty of Medicine, Ontario in 1924. He is a member of the Ontario College of Physicians, a Fellow of the Massachusetts Medical Society and the American Medical Association, the Massachusetts Psychiatric Association, American Association on Mental Deficiency and the American Psychiatric Association.

CORRESPONDENCE

ABUSE OF DIAGNOSTIC SERVICE

January 11, 1936.

Editor *New England Journal of Medicine*,

With the increasing interest in pneumonia the Department of Public Health recently arranged for laboratory service through its Diagnostic Laboratory whereby sputa from cases of pneumonia might be

typed, if necessary, at any hour of the day In this respect it is offering a service that is not available even in the hospitals of the State Since that time there has been so much unwarranted abuse of this that the Department must consider discontinuing this type of service unless the abuses are stopped.

On numerous occasions, bacteriologists of the Department have been called from their homes, sometimes after retiring for the night, to come to the laboratory to type a sputum only to find that the specimen was accompanied by a request from the attending physician that he should not be called as to the results until the following morning In several other instances, specimens have been received in which the attached card indicated the patient had been sick a week or more In some instances, hospitals have sent sputa in after the technician whom they employ had left for the evening, and in other instances it has been frankly stated that the sputum might have been submitted earlier in the day but it was simply more convenient to send it in around 10 o'clock at night

It is no more possible for the State to maintain trained bacteriologists in the laboratory twenty four hours a day than it is for hospitals to do the same The bacteriologists of the Department are glad to come from their homes to the laboratory at any hour to examine an emergency specimen but it is obvious that there can be little emergency if the physician is not willing to receive the reports until the next morning, nor can there be emergency in the typing of sputum if the patient has been sick for so long a time as to preclude the possibility of serum therapy

May I, therefore, through your columns request of the physicians and the hospitals that they send to the laboratory after five o'clock only those specimens which are actual emergencies, and that other specimens where there is no haste be reserved until the following morning Only in this way can the laboratory give the highest possible quality of service to the physicians and hospitals submitting specimens to it.

Very truly yours,

HENRY D CHADWICK, M D,

Commissioner of Public Health

RESTORATION OF THE REGISTRATION OF DR S MARGARET BROWN AND THAT OF DR. JOSEPH N TESSIER

Board of Registration in Medicine
State House, Boston

December 31, 1935

Editor, *New England Journal of Medicine*,

On December 12, 1935, the Board of Registration in Medicine restored to Dr S Margaret Brown her certificate of registration which was revoked on December 20, 1934

On December 18, 1935, the Board of Registration in Medicine, in accordance with the decree of Justice Lummus of the Supreme Court, returned to Dr Joseph N Tessier his certificate of registration which had been revoked on February 28, 1935

I am enclosing a copy of the findings, rulings and order for decree in Dr Tessier's case, by Justice Lummus

Yours very truly,

STEPHEN RUSHMORE, M D, *Secretary*

v

Board of Registration in Medicine
Findings, Rulings and Order for Decree

This is a petition under G L (Ter Ed.) c 112/64 for the revision or reversal of a decision of the Board of Registration in Medicine, revoking the registration of the petitioner as a physician, on the ground that the decision was "plainly wrong" The nature of the proceeding is discussed in *Ott v Board of Registration in Medicine*, 276 Mass 566 The matter was presented to me upon a transcript of the evidence before the Board

The authority of the Board is derived from G L (Ter Ed.) c 112/61 Its decision to revoke the registration must be based (omitting certain immaterial grounds) upon "malpractice" or "gross misconduct in the practice of his profession" The words "gross misconduct" do not include mere unfitness or unskillfulness, nor ordinary negligence See *Burns' Case*, 218 Mass 8, *Nickerson's Case*, 218 Mass 158, *Silver's Case*, 260 Mass 222, *Swardleck's Case*, 264 Mass 495

The decision of the Board was based upon the charge that the petitioner was guilty of gross misconduct in the practice of his profession in the case of Charles Szigler of New Bedford Other charges have therefore become immaterial

The evidence showed the following facts Charles Szigler, the patient, was a young man of twenty-three years, afflicted with chronic nephritis He had a high blood pressure and his urine was loaded with albumin His eyes and vision were much affected, He suffered from headaches Nephritis is a disease that becomes progressively worse

After treating with Dr Everest La Riviere from the fall of 1913 and going to the Truesdale Hospital for a thorough examination he came under the care of Dr Emil F Suchnicki on February 3 1934. The patient was confined to his bed much of the time Dr Suchnicki was unable to do anything to better the condition and ceased his attendance on March 28 1934. He had recommended a consultation with Dr Herman Groh which was had on March 15 1934. After examination, Dr Groh could suggest no curative treatment, and told the patient's sister that the case was hopeless. The patient and his family believed that he was about to die.

On April 13 1934 the patient consulted the petitioner. The patient said that he would be satisfied if his life could be prolonged for a time and he could get some comfort. The petitioner said that one kidney was bad and that he would take the chance of operating and probably an operation would help the patient. He did not predict a cure. The patient consented, saying that if he was going to die anyway he might as well take the chance. The petitioner put the patient in the Union Hospital on April 15 1934 to recruit his strength for the operation. On April 20 1934 the petitioner removed the diseased kidney. On April 30 1934 he took the patient from the hospital to his own convalescent home, and kept him there until June 9 1934. When discharged on that day the patient was much improved. His blood pressure was much reduced. He resumed many of his activities, including sea bathing. While bathing on one occasion he suffered a chill. The petitioner was called on August 4 1934. The patient died on August 24 1934.

Very likely the petitioner was in error in thinking that the patient was tubercular. Very likely the operation offered little promise, although the condition of the patient undoubtedly improved after wards.

The patient and his family wished it, and the family remain satisfied with the petitioner's efforts. It does not appear that he was actuated by the desire to earn a fee for useless work. The patient's family paid him \$325. Out of that he paid \$82 to the Union Hospital \$70 to the nurse at the Hospital and \$20 to the doctor who assisted at the operation leaving \$153. For that sum the petitioner furnished board and care for forty-two days at his convalescent home together with his services for the whole period of his care, including the operation.

On the whole I think that a finding of gross misconduct could not have been made. Let a decree be entered reversing the decision of the Board.

HENRY T LUMMUS J S J O

December 10 1935

RECENT DEATHS

HOWLAND—CHARLES A. HOWLAND, M.D. of 1303 Union Street Schenectady N. Y., died suddenly at his home on December 28 1935. Dr Howland was

born at East Worcester Otsego County, on February 25, 1877. He attended schools in North Adams, Mass. Drury Academy and Clinton Liberal Institute. He was graduated from Colgate University in 1901 after which he went to the Philippine Islands for two years as a teacher. On his return he studied medicine at Baltimore Medical College being graduated cum laude in 1908. Following his graduation he took a contract position in the North Carolina mountains, and in the fall of 1908 began practice in Fall River. In 1917 he removed to Schenectady to practice internal medicine. During the World War he was a captain in the medical corps serving as surgeon with the 37th Division.

Dr Howland was a prominent citizen of Schenectady where he organized the Schenectady Law Enforcement League. Besides his widow Mrs. Helen O. Howland he is survived by three daughters Mrs. Martha Schoonmaker of Schenectady Mrs. Robert Gantt and Miss Elma Howland of New York City.

O'CONNOR—JAMES B. O'CONNOR, M.D. of 180 Fairmount Street, Lowell, died in that city on December 23 1935. Dr O'Connor was born in 1868 and was graduated from the College of Physicians and Surgeons of Baltimore in 1898 in which year he joined the Massachusetts Medical Society.

COBB—CAROLUS MELVILLE COBB, M.D. of 44 Atlantic Street, Lynn, Massachusetts died January 2, 1936.

Dr Cobb was born in 1861 and graduated from the University of Vermont College of Medicine in 1883. He joined the Massachusetts Medical Society in 1895 and was also a Fellow of the American Medical Association.

Dr Cobb was affiliated with the Masonic Order and had been raised to the thirty-second degree.

He was a member of the Society of Mayflower Descendants.

PATTEN—STEPHEN K. PATTEN, M.D. died on January 11 at his home in Watertown. A graduate of Harvard Medical School in 1898 he was a member of the Licentiate of the Royal College of Physicians and of the Royal College of Surgeons of London.

NOTICES

BOSTON UNIVERSITY SCHOOL OF MEDICINE
SURGICAL CLINIC AT THE BOSTON CITY
HOSPITAL

Friday January 17 12-1 Cheever amphitheatre.

Dr William R. Morrison, Associate Professor of Surgery Boston University School of Medicine will present the following cases:

1. Hour-Glass Stomach Due to Gastric Ulcer on the Lesser Curvature Balfour Cantery Excision and Plastic Operation
2. Congenital Pyloric Stenosis Rammstedt Operation.
3. Comminuted Fracture of Both Bones of the Lower Leg Open Reduction and Insertion of Two Bone Bands.

Physicians and medical students are invited.

MEDICAL CLINIC AND STAFF ROUNDS AT THE PETER BENT BRIGHAM HOSPITAL

At 3 30 P M on Thursday, January 23, in the Amphitheatre of the Peter Bent Brigham Hospital, Dr Henry A Christian, Physician in Chief, Hersey Professor of the Theory and Practice of Physic in the Harvard Medical School, will give a medical clinic To it are cordially invited practitioners and medical students

On Saturdays in the wards of the Peter Bent Brigham Hospital, from 10 to 12, staff rounds will be conducted by Dr Christian

BOOK REVIEWS

The Autonomic Nervous System Anatomy, Physiology, and Surgical Treatment. James C White 386 pp New York The Macmillan Company \$7 00

This book makes a conspicuous advance in surgery. No longer is the surgical operation directed only at the removal of pathological tissue, guided by a knowledge of anatomy, but now normal structures are attacked with the purpose of changing the function of distant organs. A few such procedures have been carried out in other fields, as, for example, in the removal of the normal thyroid gland, in this book however, some twenty disease entities are discussed that may be treated by sympathectomy. The list includes such important and common disturbances as Raynaud's disease, epilepsy, neuralgia, angina pectoris, hypertension and Hirschsprung's disease. Obviously such work as this requires an intimate knowledge of the anatomy and physiology of the autonomic nervous system. This knowledge the author has in generous measure, not only from reading and dissections, but also from a long series of experiments on animals, and extensive physio-

logical observations on man. In fact one hundred and forty-three pages are devoted to anatomy, physiology and methods. These three chapters give an up-to-date summary that is better than anything the reviewer has seen in this field.

In discussing sympathetic denervations White says, "In order to produce lasting physiological results, sympathetic denervation of an extremity or viscus must be anatomically complete and carried out in such a way that regeneration cannot take place. Following an incomplete denervation, the remaining sympathetic fibres are capable of gradually increasing their activity and bringing about a recurrence of the original disorder within six months. In order to prevent regeneration, the ganglia must be removed. Ramisectomy frequently fails, not only because it is so difficult to cut all of these tiny filaments, but also because the white rami are capable of rapid regeneration. From these facts it is obvious that ganglionectomy is the surest way to achieve satisfactory and lasting results. While it cannot be denied that in resecting even a single ganglion many connections of normally functioning organs are sacrificed, this does not seem to produce any serious effect." The next sixty pages are given to descriptions of cervical, thoracic and abdominal sympathectomies, and to a description of the technique of paravertebral injection.

To internists and neurologists the most readable and valuable part of the book is Part II, where chapters discuss peripheral vascular disease, pain in the extremities, migraine and epilepsy, cardiac disturbances, asthma, gastrointestinal disease, visceral pain, dysmenorrhea and even arthritis. This gives an idea of the breadth of the subject, the whole body must be discussed (if we only stop to consider) for autonomic fibres reach every organ! But the discussions are adequate though brief, and always moderate, even modest. For the psychiatrist there are important data in the discussion of the effects of emotions upon Raynaud's disease, hypertension and angina pectoris. Indeed a new era is at hand when a surgical monograph discusses psychiatry! It is a fine book and is recommended especially to neurologists and psychiatrists, for it suggests many important problems in that no-man's-land of psychosomatic relationships.

Some Facts about Nursing. A handbook for speakers and others. Prepared by the Nursing Information Bureau of the American Nurses' Association 46 pp.

In this little book are presented, in condensed form, various facts concerning the profession of nursing in this country. The number and distribution, the marital state and the training of nurses, their salaries and opportunities, are given. The national nursing organizations are described briefly. As a reference book for those who require facts about the profession of nursing, "Some Facts About Nursing" will prove to be extremely useful.

NEW ENGLAND SURGICAL SOCIETY

ACUTE ARTERIAL OBSTRUCTION FROM ARTERITIS*

BY HOWARD M. OLUTE, M.D.†

COMplete occlusion of the lumen of a large arterial trunk by an inflammatory process within the vessel, produces symptoms not only from the failure of blood supply, but also very probably from the stimulation of the sympathetic nerve supply of the vessel by the inflammatory process in its walls. The occurrence of acute arteritis is very rare, yet the condition is one which may be readily recognized when present, and its symptoms considerably improved by appropriate treatment. The writer has had the opportunity of operating in the last few years upon two cases in the Lahey Clinic which are the basis of this report.

The subject of localized arterial obliteration has been studied extensively by René Leriche and he and his associates have carried out a considerable research on this problem. In addition, scattered case reports and discussions have been made by Braeucker in Germany, Ryle in England, and Kramer in the United States. Leriche believes that the occlusion of an artery by an inflammatory process in its walls causes a constant source of excitation of the sympathetic nerve supply of the artery and of the arterial tree beyond. In cases of acute arteritis, therefore, certain signs and symptoms will occur which are due to the loss of blood supply and others will appear because of constant stimulation of the vasomotor sympathetic nerve fibres in the artery. Leriche says the obliterated artery ceases to be an artery, and becomes a diseased sympathetic nerve.

Acute arteritis may arise during the course of overwhelming general infections, such as septicemia or pneumonia. Its occurrence no doubt is related to a slowing of the rate of blood flow in the artery, plus the presence of numerous bacteria in the blood stream. Occasionally in such cases several arteries are involved. This type of arteritis is usually a terminal event noted in the last hours of a serious illness or at the autopsy table, and does not concern us particularly in this study.

Acute arteritis may occur, it is thought, as a localized infection in the arterial wall. Almost

always this is secondary to an infection elsewhere in the body which may be far removed from the involved artery. Thus in the first case here reported, the patient had had a persistent, severe, non specific prostatitis for many months preceding his arteritis. In other patients, infection adjacent to the involved artery, as in a septic amputation stump, has been considered as the etiologic factor.

Trauma received over an artery may well be a factor in acute arteritis and repeated case reports in the literature have associated an injury with the condition. Thus a blow on the dorsum of the foot was reported in one case, a fracture in another, and the use of crutches was noted in several other instances, including my second case. Whether the trauma produces a local injury in the arterial wall which promotes an intramural clot, or whether it merely produces an area in which local resistance to infection is reduced, is a debatable matter.

This present discussion does not include cases of chronic arterial occlusion, such as syphilitic endarteritis, arteriosclerotic and atheromatous involvement of vessels and Buerger's disease.

The symptoms of acute arteritis are slow in onset and gradually become more pronounced as the process involves more of the vessel and its branches. The patient notices first a marked weakness of the arm or leg. This becomes worse with exercise, for example, our first patient found that it was difficult for him to tie his necktie or raise a window. The extremity becomes cold and with any exercise becomes blanched. In some cases cyanosis is present in the hand or foot of the affected side and excessive sweating of the extremity may be noted.

On examination it is noted that the pulsation in the involved artery is absent. The vessel can usually be felt as a tendinous cord which is definitely tender in the early stages of the disease. Blood pressure readings show no blood pressure on the affected side and a pressure normal for the individual on the opposite side. Changes in sensation occur late in the course of the disease, and trophic ulcers that are very painful and chronic have been reported. Atrophy of the muscles of the limb is, of course, associated with long disease and diminished blood supply of the part.

Read at the Annual Meeting of the New England Surgical Society at Manchester, N. H., September 23, 1935.

†Chute, Howard M.—Professor of Surgery, Boston University School of Medicine. For record and address of author see "This Week's Issue," page 161.

CASE 1 Mr E. K. was first seen in March, 1928, because of a nonspecific prostatitis and urethritis. He was thirty-five years of age. He received treatment for the prostatitis at irregular intervals for three years. In April, 1931 he returned because the prostatitis was more severe, and in addition he had noted pain and distress in his left hand. His grip was weak and he could not use his hand even for such a small matter as turning a doorknob.

In August 1931 the pain in the left hand and arm grew more severe, and blanching, coldness, and occasional cyanosis of the hand were noted. The pain in the arm had progressed upward and the patient noted tenderness over the radial and brachial arteries.

Examination showed the left arm and hand to be cold, perspiring and slightly cyanotic. With any motion of the fingers blanching occurred. No radial pulse or brachial pulse was felt. The brachial artery could be palpated as a deep, swollen, tender cord. The subclavian and axillary arteries were pulsating normally. No blood pressure could be obtained on the left side. On the right it was 145/105.

CASE 1 Photographs four years after partial resection left brachial artery for acute arteritis. No radial pulse. Diminished circulation of left arm and partial disability noted with heavy work. Arteritis had extended quite high before operation.

X-rays of the cervical spine showed an area of calcification lateral to the seventh cervical vertebra on the left. The Wassermann test was negative.

Dr Arthur W. Allen of Boston kindly saw this patient in consultation with me, and first suggested the true diagnosis of acute arteritis.

On September 3, 1931 I explored the left supraclavicular area on this patient. No glands were found that could be interfering with the subclavian vessel. The scalene tendon did not seem to press unduly on the subclavian artery, but some of its fibres were cut. Recovery from this operation was uneventful but there was no improvement in the left hand or arm.

On September 9, 1931, therefore, I explored the left brachial artery. This was found to be a firm cord with no pulsation and with definite edema surrounding it. Two inches or more of the artery were removed, and about the same amount of the brachial vein. The brachial vein was apparently normal. Microscopic study of the sections by Dr. Shields Warren showed chronic periarteritis. Antemortem thrombus formed in streaming blood. Bacteriological examination showed no growth.

Within three days after this operation all prickling and burning in the left arm and hand had ceased. The unusual sweating also disappeared and the color of the extremity was good. The arm or hand could be moved for two minutes with no pain, and this ability to use the arm increased rapidly. Three

years after the operation the patient had but slight disability in his left hand or arm. He still had no pulse that could be felt in the wrist, and no blood pressure reading was audible, but otherwise examination was negative.

CASE 2 Mr I. S., aged forty-six, was first seen in September, 1934. He stated that five weeks before he had noted soreness in his right index finger and that later blanching and numbness in all his fingers on the right hand appeared. His right arm tired very rapidly with any use so that he could neither do his work nor use the crutch which he required for walking. The patient had, himself, noticed the absence of his radial pulse, and had followed the course of the ascending obliteration of this artery from day to day.

This man had had infantile paralysis when a child

CASE 2 Six months after operation for acute arteritis. Good radial pulse. Normal use of arm. Operation done early in course of disease before process had reached high level in brachial artery.

and had a postinfantile paralysis of his right leg. He had used a single crutch for over thirty years.

On examination it was noted that the right hand and forearm were colder than the left. All motions of the joints were normal and there was no swelling. Blanching of the hand and fingers followed movements of these parts. Slight cyanosis was present when the arm was at rest. No pulse or blood pressure was noted in the right arm. The blood pressure in the left arm was 196/126. The subclavian, axillary and upper brachial artery could be felt with normal pulsations. At the junction of the upper and middle thirds of the right brachial artery, pulsation ceased and the artery could be felt as a solid, firm, tender cord below this point. Blood counts and smears were normal. A diagnosis of acute arteritis, possibly related to the trauma of his crutch, was made, and operation was advised.

On September 25, 1934 the right brachial artery was exposed for a distance of six inches. It was found to be a firm, nonpulsating cord with definite edema in its wall and in the contiguous tissues. Two inches of the artery were removed. Its lumen was filled with a thrombus.

Dr. Shields Warren's diagnosis from the specimen was as follows: Subacute periarteritis with thrombosis. Smears and cultures were negative, save for a few diphtheroids.

The day following the operation, the pain and numbness had disappeared from this man's hand. He said he could move his fingers and hand with much less distress. Improvement was rapid and continuous. A month after operation he reported that he had no further pain in the arm, and that he could use it for long periods without tiring. Four months after operation he was working again with no disability. Recent examination shows a good radial pulse in the right wrist and a normal blood pressure in the

right arm. He complained, however of a prickling and burning sensation in his hands and feet. Study showed that he was suffering from a chronic myelogenous leukemia in an acute phase. Review of the blood examination made six months before however showed a normal blood picture at the time of the onset of acute arteritis. It seems unlikely therefore that one can associate the leukemia in any way with the obliterating arteritis.

From the experience gained in these two cases, it appears that resection of part of an occluded artery as Leriche suggests has a beneficial effect both on the trophic disturbances in the limb and the establishment of a collateral circulation. Very probably the increase in the blood supply following arteriotomy is due to paralysis of the vasomotor nerves to the accessory arteries of the part. Leriche and his assistants have carried out interesting experiments to demonstrate this fact. Excellent collateral circulation usually follows the resection of major arteries in dogs, but gangrene frequently followed simple ligation of the same vessels. Leriche recommends resection of the obliterated artery for certain painful amputation stumps when the vessels were ligated in continuity, for trophic ulcers on amputation stumps and for localized arteritis and recent thrombosis in arteriosclerosis. He believes the best results occur when the entire obliterated portion of the artery can be removed. He does not recommend the procedure in Buerger's disease.

The operative procedure in each of my cases was limited to the removal of but a short piece (two inches) of the thrombosed vessel. No attempt was made to remove the entire artery and I should in the future hesitate to undertake such a procedure, first, because it does not appear necessary for good results, and, secondly because such an extensive dissection might well injure some of the collateral arteries.

The end results in the first case were not so good as in the second case. Thus, I believe, was due to the delay in recognition of the pathology in case 1 until the process had advanced well up the brachial artery to involve more of the main arterial trunk. Early interference in case 2 gave a better opportunity for the development of a good collateral circulation.

One must be impressed in these two cases with the apparent relation of the sympathetic nerves of a main artery to many of the symptoms and signs which follow its occlusion. In a recent case of guillotine amputation for diabetic gangrene, I had occasion to tie the common femoral artery just below Poupert's ligament for secondary hemorrhage in the infected stump. When the vessel was ligated, an inch or more of the artery was removed. This adds but a moment to the operation. Following this procedure there was no apparent interference with the blood supply of the stump, and within a few days there was frank oozing from raw tissue edges. Death occurred some weeks later

from septicemia, but the blood supply of the stump remained good during life. It may well be desirable in the future to remove a section of the artery when ligation of a major vessel is necessary, as recommended by Leriche and others. By this, one may not only avoid the trophic disturbances that sometimes follow a simple ligation, but may also improve the collateral circulation by paralyzing the vasospastic sympathetic nerves in the main artery.

From the experience gained in these cases it appears that resection of part of an occluded arterial trunk aids the establishment of a collateral circulation and overcomes the symptoms arising from the stimulation of the sympathetic nerves of a diseased artery.

DISCUSSION

Dr. ARTHUR W. ALLEN, Boston, Mass.: *Mr. President and Gentlemen*—I regret that I can add very little to this interesting but rare condition. I believe it is quite rare because I have not seen any other patient that had the diagnosis proved except this one that I was fortunate enough to see with Dr. Clute.

It seems to me that, if we were on the alert for such cases, perhaps quite a number might be detected.

I believe the logical way to look at this subject from the standpoint of etiology is that it probably is a combination of two factors, one, infection which may be slight, mild, generalized, overlooked. The other is trauma. I do not believe there was any history of trauma in this first case but sometimes trauma, even so slight that it may not be recalled, will produce something that is very like this in the veins. Such instances have occurred after the swinging of a golf club or a strenuous basketball game.

The other interesting feature about it is that it is not necessary to eradicate all of the infection. Dr. Clute has demonstrated that, by removal of a comparatively small segment of these vessels the symptoms disappear. This interests me because it shows that the method of cure must come about not through the removal of the infection but through some other channel, most likely the interruption of the sympathetic nerve pathways.

There isn't the slightest question but that you can interrupt the sympathetic pathways temporarily by dividing the vessel and get a temporary boost in the peripheral circulation. This has been demonstrated in a good many instances and in a number of conditions. Sometimes this temporary boost by tying a patient over the critical period pain that has been present a long time may not return.

Dr. JOHN HOKANS, Boston, Mass.: Dr. Clute has called attention to the fact that some of these cases are traumatic and some of them are due to infections at a distance—infection of a nonsuppurative sort which affects the whole arterial wall.

I think most of Leriche's cases were frankly trau

matic and many were war injuries, some quite complicated, having nerve injuries in addition I believe, therefore, that the men who see many badly crushed limbs will see perhaps more of this lesion, if they look for it, than the rest of us

There is one point which is perhaps a theoretical consideration only Dr Clute is doubtless aware of the fact that sympathetic fibers do not progress along the arteries for a very great distance But what do progress along the arteries are sensory filaments from the periphery, and although no one is sure about this, it would appear that the interruption of painful sensory impulses passing from this

inflamed area may be the factor which abolishes reflex vasomotor constriction in the extremity

I do not think that those who have studied the subject and believe in the absence of any continuous vasomotor supply running down an artery, would agree that the mechanism of improvement from resecting an artery was what Leriche has thought it to be But at any rate Leriche is to be thanked for calling attention to the fact that if one takes out a block of artery, one in some way often abolishes peripheral vasomotor spasm

I think Dr Clute's experience abundantly confirms that

HYPERGLYCEMIA AND PARESIS*

Report of Two Cases

BY L. MINOR BLACKFORD, M.D.,† AND JOHN H. VENABLE, M.D.†

SOME of the mystery surrounding diabetes, one of the oldest diseases in medical history, seemed to have been cleared up in 1857 when Claude Bernard performed his famous piqure of the floor of the fourth ventricle The following year Leudet found a gumma of this region in a case of symptomatic diabetes For some forty years after this the question of the etiologic relationship of syphilis to diabetes was kept constantly alive In 1899, Minkowski discovered almost accidentally that a pancreatectomized dog died rapidly with diabetes With the establishment of the rôle of the insular tissue in diabetes, the possible etiologic importance of syphilis in disturbances of carbohydrate metabolism subsided to perhaps too great an extent

In 1929, Lemann, after an exhaustive review of the literature and the study of some original cases, concluded that syphilis of the pancreas in exceedingly rare cases might result in the diabetic syndrome, though coexistent syphilis and diabetes are more often independent. Lemann assembled about a dozen cases from the literature in which it appeared that the clinical picture of diabetes was due to syphilis of the central nervous system, though only Leudet was able to offer postmortem evidence Dickinson, in 1874, stated, "Syphilitic changes within the skull can undoubtedly be the cause of diabetes" Labbé and Touffet said, in 1923, "It is certain that temporary glycosuria caused by lesions of the nerve centers at the base of the brain—syphilitic or not—do exist, it is probable that certain cerebral lesions can produce glycosuria in relation to permanent disturbance of glyceregulation. It is not, however, demonstrated that syphilis can cause a true diabetes by producing lesions of the nerve centers Nerv-

ous diabetes, syphilitic or not, is extremely rare"

In a recent book, Cushing pointed out that the frequent association of acromegaly with diabetes mellitus first suggested relationship between the pituitary body and carbohydrate metabolism Later experimental and clinical studies of hypopituitarism showed a surprisingly high tolerance for sugars He has suggested that the hypothalamic region is the point of origin of glycogenolytic responses rather than the hypophysis itself

Byrom and Russell have reported the case of an ependymal cyst of the third ventricle associated with diabetes mellitus While granting that it could not be unequivocally proved that the association was not a coincidence, yet in the light of the connection known to exist between hypothalamic nuclei and the sympathetic nervous system, they suggested that "chronic irritation of the gray matter of that region may have caused a sympathetic hyperglycemia of sufficient degree and duration to initiate progressive diabetes mellitus in a patient congenitally predisposed to the disease"

Bagley has reported a case in which with the electrosurgical unit he removed a meningioma growing from the dura at the foramen magnum and projecting into the fourth ventricle The patient had been treated for diabetes before the diagnosis of brain tumor was made In the first few postoperative days, among other manifestations his blood sugar ranged as high as 273 mg per 100 cc of blood "From about the tenth day there was rapid improvement and he has continued to do well with no glycosuria or other evidence of diabetes"

The presence of hyperglycemia and glycosuria in the presence of subarachnoid hemorrhage has been commented on frequently

These references suffice to establish that disturbances of the base of the brain can cause increase in blood sugar In spite of the paucity of pathologic data, it may be assumed that late

syphilis of the central nervous system can affect the same basal nuclei.

REPORT OF CASES

CASE 1—N S., an illiterate colored woman aged forty-seven, was brought into the hospital in a convulsive state the night of May 1 1932. Her relatives said that she had had severe headaches for many years, that she had been feeling badly for some weeks, with shortness of breath, cough and retrosternal pain on exertion. Four hours before admission she had started to build a fire when her hands began to tremble and jerk. A few seconds later she was seized with a generalized convulsion and there had been some heaving from the mouth she had had repeated convulsions since.

The pupils reacted sluggishly to light and the patellar reflexes were hyperactive. Catheterized urine on admission showed 4 plus sugar with acetone and diacetic acid. Blood sugar was 377 mg per 100 cc. She was thought to be in a diabetic crisis of some sort and was treated accordingly. Within twenty-four hours the urinalysis was negative and blood sugar within normal limits. Spinal fluid taken on admission gave a strongly positive Wassermann reaction an increase (2 plus) in globulin and a paretic curve with 50 cells. The Wassermann reaction of the blood was strongly positive then and it remained so during the rest of the time that she was under observation.

Antisyphilitic treatment with bismuth and potassium iodide was begun May 27 and continued at her convenience for seventeen months. There was prompt and marked subjective improvement, with gain in weight and the headache cleared up. July 14 1933 she was brought to the clinic irrational and was admitted to the hospital. Hemiplegia on the left rapidly cleared up and she was dismissed in a few days.

She had many urinalyses after her first admission and none, after May 27 1932, showed the presence of sugar. Her highest fasting blood sugar was 140. She restricted the carbohydrates of her diet. The patient did not return for further antisyphilitic treatment after Nov 3 1933. One of us saw her from time to time during the following year and it appeared that there was further disintegration of what intelligence she had and that she continued to have occasional convulsions sometimes with transient paralysis.

She had been married thirty-two years and stated that her nine living children represented all of her pregnancies. Two of these however had treatment for syphilis in early childhood.

CASE 2—F W., another illiterate colored woman about the same age as Case 1 was admitted to the hospital Aug 21 1930 in a convulsive state. Her sister stated that she had seemed all right when she returned from work at 7 P.M. She went to bed promptly but about three hours later was seized with a convulsion. After several convulsions they called the ambulance. Further inquiry revealed that she had been noticeably irritable for many months and had often walked around aimlessly much of the day. She had always been very fond of sweets but there had been no increased thirst. Urinalysis on admission was reported "sugar 4 plus, diacetic acid and acetone 2 plus." Many subsequent urinalyses were negative. Her blood sugar on admission was 250 mg. per 100 cc. Insulin in large amounts was administered and she regained consciousness within a few hours. The Wassermann reaction of the blood on the first admission was reported negative. It was noted, however that the pupils react very little to light."

She was admitted to the hospital a second time a year later on account of vague pains in neck and hips. At that time blood sugar was 100 mg.

In January 1933 the presence of Argyll Robertson pupils and of markedly hyperactive knee jerks evidenced syphilis of the central nervous system. The Wassermann reaction of the blood then and on two subsequent occasions was strongly positive. The spinal fluid also gave a positive reaction as well as a paretic curve. After a few injections of bismuth she volunteered that her head no longer ached.

On Feb 10 1933 a dextrose tolerance test was done with the following result:

Fasting blood sugar 10 a. m.	83 mg
Dextrose administered	
Blood sugar at 10 30 a.m.	142
at 11	223
at noon	375
at 1 p.m.	300

She discontinued treatment after the eighth dose of bismuth on February 23. A few weeks later she skinned her shin and an ugly ulcer developed. She returned to the dispensary on April 14 and received another dose of bismuth and a bottle of potassium iodide. The ulcer promptly healed. In the summer she reported for seven additional injections of bismuth but then the treatment was interrupted when she broke her left humerus. The bone knit uneventfully and she returned for her sixteenth dose of bismuth on Dec 5 1933. We were unable to get in contact with her again.

She died on Sept. 2 1934. According to her sister her appetite remained excellent to the end and she had grown very fat at the time of her sudden death the result of a "stroke."

DISCUSSION

The case reports are submitted not without trepidation. It is to our infinite regret that we could not secure greater coöperation from the patients or their relatives. Since one was buried before we knew of her death and the other has been lost for more than a year, pathologic study is obviously impossible. Both women were admitted to the hospital at night and the house officers, confronted with a grave emergency, can perhaps be excused for considering the hyperglycemia of diabetic origin.

When M. S. was referred to the Special Syphilis Clinic with the diagnosis of paresis and diabetes, the diagnoses were accepted without question. When eight months later F. W. was first seen in the dispensary, the evidence of syphilis of the central nervous system made her case so similar to that of M. S. that the possibility of the hyperglycemia being of syphilitic origin in both patients occurred to us.

In the first place, convulsions can only be explained in relation to diabetes on a basis of an overdose of insulin. Neither patient had ever had insulin at the time of her first convulsion. Convulsions are not infrequent in paresis, and the headaches, disorientation, and at times marked euphoria are, especially in view of the spinal fluid reports, pathognomonic of dementia paralytica. We know, therefore, in spite of the absence of necropsies that in both cases there

was extensive destruction of the brain substance it is not unreasonable to assume that the vital basal structures were damaged

The evidence against the presence of diabetes mellitus independent of the syphilis in the first case is not conclusive. We regret that a dextrose tolerance was not done either time she was in the hospital (indeed we thought it had been it was requested) and that her poor cooperation precluded its being done later. Several times her blood sugar was but slightly above normal, and urinalysis was repeatedly negative for sugar. In view of her own irresponsible state and the apathy and ignorance of her family, we doubt that dietary measures could have so well controlled true diabetes.

In the second case paresis seems to us an adequate explanation of the whole picture. F. W. exhibited glycosuria only when in a convulsive state, and in spite of excessive indulgence in sweets, she gained weight steadily until the

time of her death. Her sugar tolerance curve, though high, is in keeping with that reported from time to time in cases of cerebral lesions.

SUMMARY

Clinical reports of two cases of dementia paralytica in which hyperglycemia was noted are submitted. In one we feel that the hyperglycemia was surely secondary to syphilis of the basal nuclei, in the other we consider this probable. If diabetes were present in either case, it was of a benign type and caused little or no trouble.

THE AMERICAN NEISSERIAN MEDICAL SOCIETY*

Presidential Address

BY J. DELLINGER BARNEY, M.D.†

GONORRHEA is as old as history. It was described, and means for its sanitary control laid down, by Moses as recorded in the Fifteenth Chapter of Leviticus. Hippocrates called it strangury. To Galen, about 500 A.D., goes the credit for the misnomer, gonorrhea, by which it is still known today. The gonococcus was identified by Neisser sixty-five years ago.

In spite of the disabilities it has caused and the damage it has done since the beginning of time, so little has been accomplished in the direction of its control that it remains, as it has always been, among the most prevalent of all communicable diseases.

The United States Public Health Service¹ has determined after an elaborate survey of twenty-six millions of people, that nearly seven hundred thousand persons in this country apply annually for treatment of acute gonorrhea. "This estimate," says the report, "is obviously a minimum, because at least half the infected individuals fail to seek treatment until after their infections reach the late or chronic stages, and there is an unknown, but large group of individuals who never seek authorized medical care." It is perhaps safe to assume that nearly two million infections with gonorrhea occur annually in the United States.

Reports of the Massachusetts Department of Public Health indicate that in the female a diagnosis of gonorrhea is much more often

missed than made, that at least ten per cent of all infections in the female are in girls ranging from infancy to fourteen years of age, that twenty per cent occur in the fifteen to nineteen year age group, and that more than seventy-five per cent of all infections in the female are in girls and women under thirty years of age.

These reports indicate, further, that sixty-five per cent of the gonococcal infections in the male are in boys and men under thirty years of age, that the peak of prevalence is in the early twenties, and that more than half the infections in adult women have been incurred by marriage to uncured males.

Thus the story of gonorrhea is tragedy. It is the tragedy of public ignorance and a deplorable lack of professional interest in the control of this disease. In his metamorphosis from man to physician, the doctor has emerged retaining still the man's conception of gonorrhea as a "venereal disease", to be found only in those who, deserving their infections, are entitled to little sympathy and less medical consideration.

When the medical profession becomes properly conscious of the prevalence of gonorrhea and of the damage which it has wrought in countless women who are not prostitutes, something may be done for the control of the disease in the male. When the health officer and the physician join in telling people the truth about gonorrhea, there may be created a public demand for the better management of existing infections and for the more effective prevention of new ones. I feel confident that we shall find

*Delivered at the First Annual Meeting of the Society Atlantic City, N. J., June 12, 1935.

†Barney J. Dellinger—Chief of Service, Urological Department, Massachusetts General Hospital. For record and address of author see "This Week's Issue," page 163.

as time goes on that we can count upon an increasing coöperation of women doctors in the cure of this disease among patients of their own sex.

In November of this year, five years will have passed since the organization of the Massachusetts Neisserian Medical Society. Some forty or fifty physicians, interested in the more intensive study of gonorrhea, were at that time called together by the Massachusetts Department of Public Health to consider certain "Minimum Standards for the Diagnosis, Treatment and Control of Gonorrhea." The four hours of discussion which enveloped that meeting so inspired the group that it agreed as a unit to the proposal that a society be formed which might serve as an authoritative source of information and assistance to the medical profession in the management of gonorrhea. The proposal was offered with the argument that it is a major duty of the specialist to give to the whole medical profession the benefit of his larger experience in this field.

For two years the Massachusetts Neisserian Medical Society groped about, trying to decide what to do. It was addressed by excellent speakers. Discussions often became almost acrimonious, but they served only to expose a wide disagreement not only among physicians from outside the State but among those who met regularly in the same clinics and hospitals. Obviously but little assistance could be offered to the inexperienced by a group in which there was so little apparent unanimity.

Eventually certain of the Society's officers, impatient with the confusion and uncertainty of purpose, proposed the appointment of a Planning Board which would prepare an orderly course of action. The Society became suddenly unanimous and such a board was appointed. Thus was begun a study within the Society itself, of its own conception of gonorrhea and its management.

By the questionnaire method each member was quizzed in minute detail as to his use and opinion of the various laboratory procedures which are available in the diagnosis of the disease. There was encouraging agreement over some procedures, but complete and often disconcerting disagreement over others. The Society met to consider all the answers. A paper was prepared which was a sincere attempt to evaluate laboratory procedures, frankly casting into "outer darkness" those which seemed worthless, giving proper weight to those which seemed useful and reemphasizing the too often forgotten fact that the best of them are, after all only aids to diagnosis. This paper was published as the product not of an individual but of the Society in *The New England Journal of Medicine*, its official organ. Reprints were mailed not only to the six thousand physicians in Massa-

chusetts, but also to every judge and district attorney in the State.

Subsequently, in the same manner, the Society has studied the clinical diagnosis of gonorrhea in both male and female, and it is now attempting to discover how its members actually treat gonorrhea, and why certain therapeutic measures are better than others.

This involved some hard work. It has been participated in by most of the eighty or more members of the Society. Meetings have been devoted solely to the serious study of gonorrhea. The large attendance has been encouraging evidence of a desire to learn and to be helpful. It has been discovered that there is much to be done in the way of "debunking" the management of gonorrhea that traditional procedures may have no value in fact, that the pet methods of one physician may not be in favor with another, and that the gaps in our knowledge are appalling. However, the Society has been able to say to the physicians of Massachusetts "Out of all the chaos, we offer you this as a reasonably sound base line, as determined by our combined experiences."

One year ago this month, at Cleveland, the American Neisserian Medical Society was organized. Today it boasts 173 members from twenty-eight states, Porto Rico, and Canada. The very fact that such an association as this could have been organized for the study and improvement of the management of a disease which has been left too long to the ministrations of the quack and of the incompetent, is evidence that the physicians of the Americas have decided that something must be done about gonorrhea, the "stepchild" of medicine.

It now behooves us to think seriously and to plan wisely what we are to do. If we are to become only a society of listeners, before which individual physicians with pet theories to expound may read their papers, we might as well desert before we begin. If we are to take at their face value the objects of the Society as set forth in its Constitution, if we honestly and vigorously pursue the study of gonorrhea as a prevalent disease, as a long neglected and serious public health problem and as a social disgrace, there is hope that we may arrive somewhere.

There is need for dissemination of information among all practitioners of medicine as to the size and nature of the problem which we face. As a Society, how much do we ourselves know at the present moment, of the epidemiology of gonorrhea? How may we contribute to a more exact evaluation of the job we plan to undertake? If we are to teach, must we not know better than anyone else the things we wish to teach?

It should be our aim to lift the management of gonorrhea to the highest scientific and ethical plane. How can we improve unless we know what needs improvement? There is room

for the development of more helpful laboratory procedures. What do we really know about the gonococcus or the value or the shortcomings of existing laboratory aids to diagnosis, or of the pathology of gonorrhea?

The therapeutic armamentarium is a hodge-podge of whatever the drug houses happen to be exploiting at the moment. The very number of drugs in use bespeaks their inadequacy. Who is there who can say that a given urethral irrigant should be used at a certain strength and at a correct temperature and why? There will be a hundred others to "prove" that a hundred other strengths and temperatures are better. Are we to turn one ear to those who cry, while tradition echoes the refrain, "No meat, no spice, no fizzy drinks," and the other to those who deny the patient only alcohol, or shall we determine once and for all, on the basis of careful and thorough scientific study, the exact relationship of diet to the management of gonorrhea?

So on, ad infinitum, until we have called the roll of epidemiology, bacteriology, pathology, immunology, diagnosis, treatment, criteria of cure, education of the medical profession, in-

formation of the public, prophylaxis and preventive social hygiene.

What a vast field this Society looks out upon today! How full it is of the weeds and brambles of tradition, of prejudiced opinion, of unscientific lack of method, of ignorance and of prudery! Shall we burn it over, plow it under, till it well and sow the seed of scientific study in straight rows for a harvest of gonorrhea under control? If we do, this day will live long in medical and social history.

Let us look then to our membership, that while it shall include all those who are qualified, we keep the qualifications high. Let us include and call into consultation the epidemiologist, the bacteriologist, the pathologist, the educator, and the social hygienist. Let us do that kind of work which will attract the financial aid we shall need. Let us think seriously and plan wisely and then go to work. Tennyson voiced our attitude in his line,

"Ring out the false, ring in the true."

COSTOVERTEBRAL STRAIN*

BY LLOYD T. BROWN, M.D.†

STRAIN of a joint occurs only when that joint has for some cause or other been moved beyond the limits of its motion. Such a strain causes injury to the ligaments or capsule with its accompanying inflammation or swelling. If such a joint is so situated that it is in close approximation to or even partly surrounded by bony walls, swelling or inflammation will of necessity cause pressure on any structures which may be within those walls. The costovertebral joints are so placed that if there should be a strain it would be possible for pressure to come on the nerves and blood vessels which are in the intervertebral foramen as well as on the nerves after they have left the foramen on their way to the inferior surface of the ribs.

From the point of view of the mechanics of the costovertebral region it is of importance to note that there are great variations in the shape of the ribs, the vertebrae and the transverse processes in different individuals at the same vertebral level. There are also great variations in different parts of the spine in the same individual.

There are two articulations of the rib with the vertebra (fig 1), one with the vertebral

body or bodies, and one with the transverse process. Above the tenth dorsal vertebra the

FIG 1. A dorsal spine showing marked hypertrophic changes. Note that the articulation of the ribs crosses the intervertebral fibrocartilage.

*Read at the meeting of the American Academy of Orthopaedic Surgeons, January 15, 1935.

†Brown, Lloyd T.—Orthopedic Surgeon, Faulkner Hospital. For record and address of author see *This Week's Issue* page 163.

articulation with the vertebral body crosses the intervertebral fibrocartilage and has its joint attached to the upper margin of one vertebral

body, and to the lower margin of the body above. Both the vertebral and the costovertebral articulations are gliding or arthrodial joints. The articular capsule of the former is composed of short strong fibres holding the head of the rib to the vertebral bodies and intervertebral fibrocartilage (fig 2). This cap-

FIG 2. Ligaments of the costovertebral joints. Brown Gray Anatomy 2nd edition, p. 288

sule is reinforced by the radiate ligament which digitates with the anterior surface of the vertebral bodies compressing the joint and the fibrocartilage. Within the joint is found the interarticular ligament which attaches the intervertebral fibrocartilage to the head of the rib. The articulation with the transverse process, usually absent in the last two ribs, varies somewhat in its position depending upon the particular anatomic structure of the individual and on the region involved. In the slender type the articulation will more commonly be found upon the anterior aspect of the transverse process while in the heavy type of anatomic structure it will more commonly be found on the superior aspect. In some individuals (fig 3) the transverse ar-

FIG 3. Shows the variations of the position and shape of the articular facets on the transverse processes.

tication will be on the anterior aspect and at other levels it will be on the superior or even the lateral aspect. The shape of the facets on the transverse process will vary from the flat to the cup shaped or crescentic. They may face anteriorly or diagonally upward and forward, or outward, and downward at some levels. Upon the position of the facets will depend the shape of the chest when the body is in the relaxed position or that of faulty body mechanics. For

example (fig 4), if the articulation is on the anterior aspect the whole chest or rib cage can droop downward so that the ribs are nearly vertical, making the chest very long and narrow with a narrow subcostal angle. This type of chest is commonly seen in the slender anatomic

FIG 4. Anterior view of the chest.

B. The rounded chest commonly seen in the heavy type. Note that the first rib is nearly horizontal.

type. If the articulation (fig 5) is on the superior surface as is commonly found in the heavy structure the chest as a whole cannot sag downward nearly so much, the ribs do not become so vertical, the subcostal angle does not become acute and the chest is never so long as is found in the slender type. Nevertheless in

FIG 5. Posterior view of same chests

either type if the costovertebral joints are used in a position at the extreme of their motion, strain with the accompanying symptoms is equally possible.

The articular capsule holding the tubercle of the rib to the transverse process (fig 6) is thin

FIG 6 Ligaments attaching the rib to the transverse process
From Warren's Handbook of Anatomy, p 116

and entirely different in character from that at the articulation with the vertebral body. There are several ligaments which strengthen this articulation, the anterior transverse going from the neck of the rib below to the transverse process above, a ligament which could mechanically be strained very easily, the posterior transverse, similar in location but feebler and posterior to the anterior costotransverse ligament, and the middle costotransverse ligament attaching the neck of the rib to the adjacent transverse process and the ligament of the tubercle of the rib.

The ribs are so firmly attached to the vertebral bodies that extensive movements do not occur under ordinary circumstances. In respiration only a slight gliding motion occurs. With more forceful respiration or in muscular effort involving the abdominal musculature a torsion movement of the ribs takes place with the axis of motion along or just internal to the neck of the rib. With the body held in the drooped position so that the chest is in a position of nearly complete expiration there must be a considerable strain not only on the costovertebral joint because of the leverage action of the rib on the transverse process which acts as a fulcrum but also a strain on the costotransverse joint as well (fig 7). This can be demonstrated in the x-ray by evidences of hypertrophic changes along the margins of this joint. Similar changes can be seen at the costovertebral joints as well. When such changes are present there must be limitation of the motion of these joints and this

limitation, combined with the drooped position of the chest, constitutes a still greater potential of strain if there is any extra exertion or sudden unguarded movement.

FIG 7 Posterior view of costotransverse joints showing marked hypertrophic changes as evidence of strain (A) See also fig 1

It is important to understand the anatomy of these joints and the structures in their immediate vicinity in order to appreciate the possible symptomatology caused by a strain in this

FIG 8 Shows hypertrophic changes in the intervertebral foramen with a consequent narrowing of the size of the foramen.

region. The articular processes of the dorsal vertebrae form the posterior border of the intervertebral foramina. Therefore strain of these

joints may cause inflammation of the ligaments or capsule which will in turn cause pressure on the artery, veins, or nerves which are normally in the foramen. Fortunately the foramen is very large so there is usually more than enough room. Anatomical specimens (fig 8), however, show frequent evidence of hypertrophic changes along the margins of these joints which must narrow the foramen. As the nerve (fig 9) leaves the

slight pressure over a long period of time may cause interference with the blood supply or the nerves which come out in that region. Such an understanding makes it possible to see why surgeons like the late Dr. Carnett felt that a great many of the obscure thoracic and abdominal symptoms for which there seemed to be no local or visceral pathology could be explained by pressure on the nerve roots. It also makes it

DIAGRAMMATIC SECTIONS OF COSTOVERTEBRAL JOINTS AND INTERVERTEBRAL FORAMINA

intervertebral foramen it goes outward and upward in close proximity to the capsule and the tip of the articular process, so close in fact that it is hard to understand why there are not more symptoms than are commonly found. From this point the nerve continues outward and upward along the neck of the rib close to the costotransverse joint of the rib above where it finally enters the groove on the under side of the rib.

When it is seen how close to the bone the nerve is and how taut the ligaments and capsule of the joints must be in the drooped position, it is possible to understand how the torsion of the ribs in faulty body mechanics may cause acute strain on these nerves, or how a

possible to understand why these obscure symptoms disappear with the correction of the faulty body mechanics. Reasoning on this same basis we may have a very strong contributory cause for such obscure conditions as shingles, intercostal neuralgia and pleuritic pains not of pleural origin.

In conclusion, we feel that there is sufficient anatomical and clinical evidence to show that in the drooped position of the thorax seen in faulty body mechanics, it is possible to get pressure or stretching of the intercostal nerves with radiating pain along the nerves involved. This pressure may come from acute or chronic inflammation due to strain of the costovertebral or the costotransverse joints.

TWO CASES OF DWARFISM*

BY HAROLD L. HIGGINS, M.D.†

CASE 1

THIS patient is a young woman, twenty one years old. She is a cretin who has received practically no thyroid gland therapy. She is one of a family containing several children. There is no family history of thyroid disturbance or cretinism. At the age of eleven she was admitted to the Massachusetts General Hospital because of trouble with her teeth. At that time the child was given thyroid gland for a few weeks, but it was discontinued when she went home. Six months ago, at the age of twenty-one, she was again brought to the hospital because of trouble with her teeth. Again she was put on thyroid treatment and observed for a period of four weeks. On discharge home, again the patient was taken off thyroid and has received none since. Apparently the thyroid was discontinued in each case because the mother thought that the child did not react well to the medicine.

Cretins seem to see only the happy side of life. They smile and, with their poor insight, fail to have troubles and worries. Giving them thyroid gland is like opening up Pandora's Box. They begin to

realize trouble as well as to show improvement in intelligence and ability. This mother preferred that the child remain a contented baby for twenty-one years rather than be a somewhat irritable, discontented child.

With the patient at her age and her present mental capacity, full doses of thyroid gland—i.e., sufficient to cause a normal basal metabolism—would lead to a marked emotional upset and would make the child almost intractable at home. My recommendation now on this case would be the giving of approximately one seventh of the usual dose of thyroid gland for the present. That would tend to overcome her myxedema, relieve her constipation and produce a better proportioned child, but not so irritable a child as if the full dose were given. The probable full dose to overcome all signs of hypothyroidism would be approximately $1\frac{1}{2}$ grains of Armour's Thyroid daily. The optimum dose could be assayed by following her basal metabolism. One seventh of the usual dose, thus, would be $1\frac{1}{2}$ grains once a week.

The word "cretin" etymologically means "dwarf." This child is certainly a dwarf, her height being forty one and one-fourth inches instead of the normal of about sixty three.

In making a diagnosis of cretinism in the Children's Clinic at the Massachusetts General Hospital, we use the form which follows, the findings with

*These cases were demonstrated at the meeting of the New England Pediatric Society March 22, 1935.

†Higgins, Harold L.—Chief of Children's Medical Service, Massachusetts General Hospital. For record and address of author see "This Week's Issue," page 163.

CHARACTERISTIC SIGNS AND SYMPTOMS

	Before Treatment	After 4 Weeks' Treatment
Dwarfed	+ $41\frac{1}{4}$ inches	+ No Change
Center of body higher than usual	+ At umbilicus	+ " "
Extremities—short.	+ " "	+ " "
Square hands. Short fingers	+ " "	+ " "
Delayed dentition	+ 10 years	+ " "
Delayed calcification of bones of wrist.	+ 6 years	+ " "
Delayed closure of fontanelles	+ Ant. Font. Open	+ " "
Doughy, gelatinous, pale to yellow skin (Myxedema)	+ " "	o Lost 8 lbs. in wt.
Dry skin, scaly, no perspiration	+ " "	o " "
Puffy face, thick eyelids	+ " "	+ No Change
Depressed nasal bridge	+ " "	+ " "
Coarse, sparse, dry hair	+ " "	? Change
Sparse eyebrows	o " "	o No Change
No pubic or axillary hair	+ " "	+ " "
Tongue—thickened and enlarged	+ " "	o " "
Mucous membranes thickened	+ " "	o " "
Lips thick and prominent	+ " "	o " "
Neck—pads of fat	+ " "	o " "
Heart—rate slow	+ " "	Disappearing
Abdomen—protruding (lordotic posture)	+ $30\frac{1}{4}$ inches	+ Rate faster
Umbilical hernia	? " "	Less $26\frac{1}{2}$ inches
Tendency to constipation.	+ " "	? No Change
Speech—delayed	+ " "	+ No Change
Voice—deep and coarse	+ " "	o Higher pitched
Grunts	+ " "	+ Less
Voluntary motions—slow	+ " "	+ " "
Walking—delayed, unsteady	+ " "	? Change
Expression—apathetic, complacent	+ " "	Less
Occasionally anxious	+ " "	+ No Change
Intelligence—backward mentally	+ Mental age 20 mos	+ " "
Disposition—happy but no insight	+ " "	o Irritable
Memory poor	+ " "	+ No Change
Easily guided (no negativism)	+ " "	Not cooperative
Not easily taught	+ " "	+ No Change
Body temperature subnormal	o 99°	o " "
Basal metabolism subnormal	+ -26%	o $+12\%$
Anemia—secondary	o " "	o " "
Blood cholesterol—high	+ 587 mg	o 250 mg

this patient before and after thyroid therapy are included.

We mark positive findings of cretinism "+" and those absent with a "o". After the examination we then evaluate the symptoms to decide as to whether the child is a cretin. In this case nearly all the signs and symptoms are present. Some of them however had disappeared after four weeks treatment with thyroid gland.

Many cretins will show as few as one-half of the signs and symptoms listed. After treatment with thyroid gland, one is often unable to tell whether the child is a cretin. In treated cases not previously seen the only method of diagnosis is to discontinue the thyroid gland for six to eight weeks and observe whether the signs and symptoms recur. We make it a rule to have a photograph of our patients before thyroid is administered. In this way we can always refer back to the appearance of the child if a question arises as to diagnosis after the treatment with thyroid has begun. In demonstrating the present patient her size and slow motions are unusually characteristic. This patient's smile is what one would expect to see in a slow motion moving picture.

It frequently happens that the question is raised whether a child is a cretin or a mongol. The differential diagnosis should present no difficulty if one evaluates the case from the differential characteristics given below.

POINTS IN THE DIFFERENTIAL DIAGNOSIS BETWEEN

	CRETINS	MONGOLS
Condition apparent	3-5 months of age	At birth
Height	Dwarfs	Normal
Body proportions	Short extremities	Normal
Hands and feet	Square short	Short thick curved in little finger hiffid tendency in hands and feet
Closure of fontanelle	Greatly delayed	Some delay (? rickets)
Teeth	Delayed eruption	Possible delay in eruption Peg-shaped teeth
Joints	Normal	Extremely flexible
Skin	Dry doughy thick myxedematous	Soft shiny smooth frequently chapped
Color of face	Pale yellow	Red as if painted
Perspiration	Lessened or absent	Normal
Hair	Sparse thick brittle	Fine soft scanty
Eyelids	Pseudo-edematous thick narrow slit	Slit turned up and out epicanthic fold present
Nose	Bridge depressed mucous membrane thick	Wids depressed bridge button like and
Mouth	Thick lips large tongue	Normal size fissured tongue usually protruding and with small tip
Expression	Apathetic or anxious forehead wrinkled face puffy and full	Cheerful comic or stupid
Heart	Slow rate	Frequently congenital malformation
Speech	Delayed deep bass voice	Delayed difficulty in pronouncing cer- tain letters
Effect of Thyroid Therapy	Rapid improvement of all symptoms	Improvement of constipation hernia, and dentition only
Infections	Usually normal resistance	Very susceptible to and with poor re- sistance to disease
Prognosis as to intelligence	Improvement with early and contin- ued treatment with thyroid gland	I Q almost never above 65 intelli- gence probably not affected by thy- roid gland therapy

CASE 2

Male child Age one year six months nine days
P H. Mother is said to have been shocked by light-
ning two months before the baby was born.

P H. Father mother and three siblings are well and
of normal development.

Birth was normal at term weight 3 lbs 7 oz.
He was not breast fed on account of his moth-
er's illness. He was fed on "Lactogen" during
the first few months of life. Cod liver oil and
orange juice were given. Later other food was
given to him. He was being fed at the time of
admission to the hospital, Grade A milk 4 oz. at
a time, five or six times a day. He also had oat
meal tomatoes potatoes and cod liver oil.

His appetite has always been poor. He has one
to two stools daily which are not unusual. He
never has had diarrhea or digestive disorder.

He had pneumonia at two months.

He will stand with support.

He says papa and mama.

P I. The patient was brought to the hospital be-
cause he did not develop physically as did his
brothers and sisters. One physician had said
he had "water on the brain".

This patient is a dwarf—a symmetrical dwarf. His
size at the present time is that of a child of six
months whereas his chronological age is eighteen
months. The child was small when he was born. He

might have been called a premature baby, but such is hardly the case since he was born at term. He was just a small baby. It is observed that the small babies, whether dwarf as this child or one of twins

Photograph shows patient at the age of twenty-three months beside a boy of normal size age twenty five months

or triplets, tend to do better nutritionally than do premature infants of the same size. They eat and utilize their food better. This child, on growing

up, will become a midget such as we see on the stage

	Patient	Normal
Weight	10 lbs	24½ lbs
Height	25¾ in	31¼ in
Head	16¾ in	18½ in.
Chest	14½ in	18½ in
Abdomen	12¾ in	17 in

Mental tests show this patient mentally to be little better than the twelve-months level. Pituitary dwarfs or midgets ordinarily are approximately normal mentally.

The cause of his small size is probably some deficiency in the pituitary gland. He is smaller and younger than are most pituitary dwarfs when first diagnosed. The problem arises—what should we do about treatment? Treatment, if attempted at all, would be by a pituitary gland preparation. Does one want him to grow up or does one want him to remain a midget? If one could get him to grow faster, he probably would not grow sufficiently to become a normal size, but he might no longer be a midget and thus lack the earning power of that group on the stage.

We have been injecting every other day 2 cc Anterior Pituitary Extract, Squibb's, hypodermically. Up to six weeks we were not able to notice any definite spurt of growth from this treatment. In giving this treatment, one has a bit of hesitancy. The preparations of growth hormone alone are reported not to have much potency. In taking the whole anterior pituitary extract one is also giving a sex hormone and there is a question of possible premature closure of the epiphyses and perhaps a result opposite to that one would try to get. Dr Hoskins advised going ahead and trying for any growth value that could be obtained from this pituitary product we have been using.

In passing we might mention the almost complete absence of nasal sinuses in pituitary dwarfs, with the prevalence of upper respiratory infections in New England, the pituitary dwarf seems to have something to be thankful for.

THE THERAPEUTIC VALUE OF CALCIUM SALTS IN SERUM SICKNESS*

BY THEODORE J. CURPHEY, M.D.,† AND SAUL SOLOMON, M.D.†

CALCIUM salts have long occupied a place in the symptomatic treatment of serum sickness. The literature, however, contains few reported investigations as to their therapeutic value and even these reports are inconclusive because the results were estimated largely on subjective criteria. Moreover, apparently none of these studies have included observations on a parallel group of untreated cases studied un-

*From the Fourth Medical Division, Bellevue Hospital. Dr. Charles Nammack, Director.

der similar circumstances and at the same time. Because of this lack of controlled investigation, inconclusive evidence and conflicting results, a carefully planned study to determine the value of calcium therapy in serum sickness seemed desirable.

An opportunity to make such a study arose in connection with an investigation into the therapeutic value of certain antipneumococcus sera conducted on the Wards of the Fourth Medical Division of Bellevue Hospital during the season 1933-34, and through the courtesy of Dr. Alexander Lambert and Dr. Charles Nammack, Director of the Division.

METHODS OF OBSERVATION

A series of patients suffering from pneumococcus lobar pneumonia was treated intramuscularly with unrefined antipneumococcus horse serum prepared by a modified method¹. These patients were tested for sensitivity to normal horse serum, and none are included in this report who showed positive skin or conjunctival reactions prior to serum administration. Of these serum treated patients, those who developed serum sickness were divided into two groups (a) those receiving calcium along with other symptomatic treatment, (b) those given the same symptomatic treatment but without calcium, alternate cases being chosen in the order of their development of serum sickness. The control cases received treatment as follows: adrenalin M. X subcutaneously p.r.n., ephedrine gr. $\frac{3}{4}$ t.i.d. by mouth, calamine lotion with phenol locally and sedatives as required. No special diet was prescribed. The cases treated with calcium received in addition to the above, varying doses of calcium gluconate. Thus, as soon as the patient developed a rash, the alternate patient was given 10 or 20 cc. of 20

per cent calcium gluconate (Sandoz)* intravenously and supplemented by 10 cc. of 10 per cent calcium gluconate intramuscularly, followed every twelve hours by 10 cc. of 10 per cent calcium gluconate intramuscularly until the rash or other symptoms subsided. In the administration of the drug, the solution for intravenous injection was warmed to body temperature and injected slowly, 10 cc. requiring two to three minutes for administration. These precautions are advocated by Lieberman² to prevent possible reactions. Such reactions are characterized by a burning sensation over the entire body, a salty taste and a feeling of weakness and nausea. Only the 10 per cent solution was used for intramuscular injection the 20 per cent product being reserved for intravenous injection.

In order to obviate as much as possible the psychological effects of the treatment, our conclusions are based primarily on the average time required for the disappearance of the rash in each group, although the occurrence and course of various other symptoms were also observed and recorded.

Table 1 shows a total of thirty patients observed.

Discharged with subjective evidence of serum sickness.
†Serum sickness present at time of death.

seived, fifteen were treated with calcium, the remaining fifteen constituted the control group. The two groups are reasonably comparable in respect to age, sex and quantity of serum administered. Moreover, if the severity of the symptoms at onset of serum disease be graded from 1 to 4 plus, it is seen that the two groups are also similar in this respect. Table 2 shows that in both groups there was a fairly uniform

TABLE 2
SHOWING AVERAGE VALUES FOR CONTROL AND
CALCIUM TREATED CASES

	Calcium Treated	Control
No. of cases	15	15
Average amount of serum administered to each case	412 cc	425 cc.
Average date of onset of rash following the first dose of serum	8.3 days	7.8 days
Days of rash	2.9 days	5.4 days
Days of subjective symptoms	3.3 days	7.1 days

time of onset of the serum sickness in that all patients showed symptoms beginning either on the eighth or ninth day. Thus, the only variables are the duration of the rash and the subjective symptoms in each group.

From table 2 it is seen that the average duration of the rash in the control group was 5.4 days as contrasted with the shorter period of 2.9 days in the calcium treated cases. Considering in addition the subjective symptomatic improvement, the difference between the two groups is even more striking, the average duration in the control group being 7.1 days as compared with 3.3 days in the calcium treated group.

Despite the small number of cases we believe that these observations are reliable. Our figures are conservatively stated, because in the compilation of the tables there were three cases in the control group where the patients either died or were discharged before the serum sickness had run its course, whereas there was only one such case in the calcium treated group. These cases are so listed in the table. Moreover, considering the development of further manifestations of serum sickness such as arthritis, giant urticaria, cramps, etc., subsequent to the onset of the rash, it was found that six of the fourteen control patients developed new symptoms while only one in the calcium treated group showed any such progression in the clinical picture.

DISCUSSION

While the value of calcium therapy in atopic disorders, particularly bronchial asthma and urticaria, has been the subject of much con-

troversy, nevertheless, Cantarow³ says that calcium salts are extensively employed in the treatment of these conditions and there can be no doubt of their beneficial effects in many cases.

The rationale of calcium therapy in serum sickness is based largely on the alleged ability of calcium to decrease vascular permeability, allay nervous irritability, constrict peripheral capillaries and raise blood pressure. Hanzlik⁴ states that calcium salts prevent or inhibit clinical allergic manifestations owing presumably to their power to lessen cellular permeability. Numerous experimental studies have been made to determine the effect and mode of action of calcium salts in serum sickness and allied conditions, but the results of these studies are by no means in agreement.

Besides these experimental studies there are clinical reports that are similarly conflicting. Thus, Thommen⁵, on studying a rather limited group of allergic diseases including several cases of urticaria and one case of serum sickness, emphatically denied the therapeutic value of calcium salts. Similarly, Hallam⁶ found calcium disappointing in the treatment of urticaria. Hunt mentions the use of calcium salts in serum sickness but is not enthusiastic as to their value.

Probably the earliest report on the value of calcium salts in serum sickness is that of Wright⁷ in 1896, himself a victim of severe serum sickness following antitoxin administration and who noted remarkable improvement following the ingestion of calcium chloride. More recently Bremer⁸, Diasio⁹, and Sterling¹⁰, have reported favorably on the value of calcium in serum sickness. Similarly, Karrenberg¹¹ reports several cases, among them that of a physician who after the injection of a prophylactic dose of tetanus antitoxin developed an extraordinarily severe serum sickness with high fever, marked exanthem and collapse symptoms. At the acme of the disease, 10 cc of 10 per cent calcium gluconate was injected intravenously and 10 cc intramuscularly. The symptoms subsided almost instantaneously. This case parallels that of B. M. in our series who developed a severe generalized urticaria associated with fever, headache and general malaise. Following adequate calcium medication associated with other symptomatic treatment as outlined above, the rash and other symptoms disappeared within three hours after onset.

In the therapeutic use of calcium salts certain conditions must be observed if the best clinical results are to be obtained. Thus, Karrenberg calls attention to the importance of administering adequate amounts of calcium in readily available form and in urticaria recommends as much as 30 cc of the 10 per cent calcium glu-

conoto solution daily, in one case of serum sickness he used 10 cc intravenously supplemented by 10 cc intramuscularly and twelve hours later gave another intramuscular injection of 10 cc. This recommendation of dosage and mode of administration is confirmed by Schaffler¹³ who showed that the intravenous use of calcium gluconate supplemented by intramuscular injections is the most satisfactory means of obtaining a sustained increase in the blood calcium level. While calcium gluconate may be administered by mouth, it is well to remember that with oral dosage, a number of factors may delay or prevent absorption from the intestine including the possible formation of insoluble calcium soap. Consequently when reliable rapid intense and prolonged calcium action is required in such acute, distressing conditions as serum sickness, the combined intravenous and intramuscular mode of administration is preferable. Apparently there is a close connection between the quantity of calcium given and the results obtained with it. Thus, Hunt reports some alleviation of the disease following the use of one Gm. of calcium gluconate intravenously t.i.d. This contrasts sharply with the recommended dosage of Korrenberg as well as with the dosage employed by us. Thus in case N E 08 much as 30 cc of the 20 per cent solution was given intravenously in one dose with simultaneous injection of 20 cc of the 10 per cent solution intramuscularly along with six Gm. of calcium gluconate by mouth a total of fourteen Gm. This dose was not followed by any untoward effect. The average case however received an initial single dose of five Gm parenterally, followed by one Gm intramuscularly every twelve hours. While a few of our earlier cases were treated with calcium gluconate orally this route was abandoned subsequently because of the uncertainty of absorption.

In conclusion this study seems to show that calcium medication in serum sickness shortens the duration of both the rash and subjective symptoms, in addition it appears to act as a preventive of such further manifestations of this disease as arthritis, giant urticariae enlarged glands, etc. These apparent beneficial results of calcium therapy well warrant further study of this interesting subject.

SUMMARY

- (1) Alternate cases of serum disease have been treated with calcium gluconate by intravenous and intramuscular injection in sufficiently large doses
- (2) Using a purely objective sign (fading of rash) as the criterion for therapeutic effect, it was found that whereas in the control cases the rash persisted for an average period of 5.4 days, in the calcium treated group it lasted only 2.9 days
- (3) Using subjective evidence as a criterion the therapeutic effect of calcium is still more striking, for in the control cases the symptoms (itching arthralgia, headache, cramps, nausea etc.) lasted 7.1 days but in the calcium treated cases the duration was only 3.3 days
- (4) Unfavorable reports in the use of calcium salts for serum disease are in all probability the result of insufficient administration of readily assimilable preparations
- (5) The alternate case method of treatment offers a better means of estimating the therapeutic value of a drug than the treatment of an uncontrolled group

TRACY B MALLORY, M.D., *Editor*

CASE 22041

PRESENTATION OF CASE

A fifty-nine year old colored American woman was admitted complaining of cough, weakness, and vomiting

About three months prior to admission the patient had severe sore throat which persisted for about a week and was followed by a cough which gradually increased in severity and frequency. At the same time there was progressively increasing expectoration and for about three weeks before entry she raised approximately two teaspoonfuls of yellowish-white frothy material every ten or fifteen minutes. This material seemed to come up to her throat without exciting a cough and she coughed only to bring it out. There was no postural or morning increase of expectoration. There were no sleep disturbances, hemoptysis, or chest pain. About two months after the onset of her illness she developed tenderness in the midepigastrium which was associated with anorexia. The loss of appetite improved but the soreness in the abdomen continued. A week before entry the anorexia returned and was associated with nausea after meals. Two days later she began to vomit a cupful of greenish bitter material before breakfast. Occasionally she vomited recently ingested food directly after other meals. There was no hematemesis or severe abdominal pain. Her weight decreased from 182 to 164 pounds during the three months of her illness. She became rather weak but spent only the two days preceding her admission in bed. During this time she had slight pain in her shoulder upon movement. There were no chills or fever although she thought that she perspired somewhat more than she did previously, especially at night. She had had some slight dyspnea with exertion for several years.

A hysterectomy for uterine fibroids was done fourteen years before entry. An x-ray at that time showed a rather tortuous aorta with a heart slightly enlarged downward and to the left. Six years later a slowly growing cyst of the parotid of some twelve years' duration was removed.

Physical examination showed a well-developed and nourished Negress. The skin was hot and dry. Oral hygiene was poor. The left border of cardiac dullness was 10.5 centimeters from the midsternal line, the right only one centimeter. The supracardiac dullness was 7 centimeters in width. The heart rate was 120 and the rhythm regular. There was a high pitched systolic murmur best heard at the left border of the sternum between the third and fourth ribs. A₂ was present but indistinct. The blood pressure was 140/70. The lungs were clear. An occasional peristaltic sound was heard under the sternum at the fourth interspace. The whole upper abdomen was rather tense and tender. The aorta could be felt pounding violently in the abdomen but no murmur was audible over it. Vaginal examination showed only the stump of the cervix, which was not remarkable.

The temperature was 101°. The respirations were 25.

Examination of the blood showed a red cell count of 4,260,000, with a hemoglobin of 100 plus per cent. The white cell count was 10,650, 68 per cent polymorphonuclears. The stools were negative. A Hinton test was negative. An electrocardiogram showed a sagging S-T₁ with slight inversion of T₃. Lead 2 was not properly standardized.

X-ray examination of the chest showed the heart to be considerably enlarged, more marked in the region of the left ventricle. The aorta was quite tortuous. The lung fields were clear. A gastrointestinal series showed no lesion of the stomach or duodenum. There was a small hernia of the cardia through the esophageal hiatus. A filling defect in the esophagus was considered to be of extrinsic origin, probably resultant upon a localized tortuosity or aneurysm of the aorta. A Graham test was negative.

The patient's temperature remained between 99° and 101°, and the pulse between 90 and 110. She continued to complain of anorexia and also some vague substernal distress. Eight days after admission she had anuria for twenty-four hours. While in the lavatory she fainted. When seen five minutes later she was found to be unconscious and flaccid. The respirations were 20 per minute and regular. The heart had a rate of 80 and the sounds were feeble and regular. The neck veins were distended. Attempts at stimulation were of no avail and she died ten minutes later. The heart continued to beat a few seconds after respirations had ceased.

DIFFERENTIAL DIAGNOSIS

DR WILLIAM B BREED. I am going to discuss this case in two phases. Having given it considerable thought and having suffered a lot

of mental anguish over it, at 10 30 last night I decided that a diagnosis could not be made. Furthermore, I felt that if I even mentioned the diagnosis in differential I should consider myself lucky.

This history is reminiscent of the various stories we have heard here lately. It is possible that the increasing cough might be a small cervical gland following tonsillitis which was discharging into the pharynx, but I think that is rather far fetched. One gathers that the trachea may have been irritated and in certain ways the story brings to mind the famous Hartford case we had here two or three weeks ago in which we found the stomach and colon in the left pleural cavity. There is nothing here which leads to any one certain diagnosis. We can say that she has esophageal irritation possibly some obstruction, and some tracheal irritation, which brings up the question as to whether she has an aneurysm. There is the question, again, as to whether she has a diaphragmatic hernia. There is a significant absence of real pain here which I think is important in ruling out some of the conditions that occur to me.

The loss of weight is perfectly consistent with the fact that she has not been eating much. The slight pain in the shoulder might make one think of some reference from the diaphragm, but when they say that the shoulder hurts on motion that rather leads one away from diaphragmatic reference.

A diverticulum of the esophagus occurs to me on reading this over. Later on you will find that there is no diverticulum according to x ray and other findings.

Then there is the question of the soreness in the midespigastrium. That of course could go along with the possible diaphragmatic hernia. It could go with an abdominal aneurysm. I am only mentioning these various possibilities that occur to me in the history before going on to further examinations.

The past history is really not very important except that it does indicate that she may have had some hypertension, the x ray fourteen years previously showed a tortuous aorta with a heart which was slightly enlarged downward and to the left, presumably on a hypertensive basis. The slowly growing cyst of the parotid removed twelve years previously, with no recurrence, I think is of no importance.

"The supracardiac dullness was 7 centimeters in width." That may or may not be of any importance. It is probably the one physical finding in which there is more error made than any other that I know of. It is important to determine when there is demonstrable supracardiac dullness what the location of it is, either

to the right or left, in seeking a possible aneurysm.

The high pitched systolic murmur means nothing to me at all. Nothing is said about its being persistent and having relation to breathing, and it seems to me without any other findings we must pass it off as being of no help in interpreting the cardiac findings.

The peristaltic sound under the sternum is, in my opinion, not significant because peristaltic sounds are heard in the chest frequently without necessitating a diagnosis of diaphragmatic hernia with the stomach in the chest, but that is a perfectly good lead.

All of these laboratory data are very interesting but they do not confirm any one of the various diagnoses that one thinks of in the history, namely thoracic or abdominal aneurysm, diaphragmatic hernia, or possibly a diverticulum high up in the esophagus. It is very interesting that no mention is made of the urinalysis or blood chemistry. I have to assume that she has no uremia.

She had a temperature by month ranging to 100°, once to 101°, a pulse of 90 to 100, and toward the last the respirations were high, up to thirty, not a very impressive looking chart. She has no anemia and no significant evidence of infection. The white cell count was 10,650, with 68 per cent polymorphonuclears. One would certainly think, if this turns out to be a uremic death, that she would have had at this time some anemia.

The best we can say about the electrocardiogram is that it does not indicate any severe coronary disease at the present time, nor any evidence of occlusion in the past, and that it is not of significance, except negatively.

"A gastrointestinal series showed no lesion of the stomach or duodenum." That is important.

"There was a small hernia of the cardia through the esophageal hiatus." That is not an uncommon finding and probably is of no significance in this particular case. Certainly at the time the x ray was taken there could have been no large diaphragmatic hernia and no thoracic stomach or colon. It says, "A filling defect in the esophagus was considered to be of extrinsic origin, probably resultant upon a localized tortuosity or aneurysm of the aorta."

Will you speak about the x rays, Dr. Holmes? Dr. GEORGE W. HOLMES. Studying the films in the brief period that I have had does not lead me to any conclusion. I might go over some of the films briefly.

Here are the gallbladder films. A perfectly normal appearing gallbladder is seen in all the films.

The chest film shows normal motion of the diaphragm on both sides. There is no evidence

of fluid in the pleural space. The lungs are of normal brilliancy. The heart is definitely increased in size and I should say that the greatest increase was downward to the left in the region of the ventricle, with moderate increase in the supracardiac shadow, perhaps due to tortuosity of the aorta.

We will look at some of the lateral and oblique views. Here is one showing the esophagus filled with barium. It shows the aortic knob fairly well. There is some calcification in the walls of the aorta, also an indentation here which I do not think is the one we are interested in. Probably this is the area discussed in the notes. This is the small hernia of the stomach described. A view in the opposite direction shows a mottled defect in the shadow of the esophagus but no actual irregularity of outline. This film shows the hernia with narrowing of the esophagus at this point.

In this film you see the arch of the aorta fairly well, and here the esophagus partially filled with barium. Such a defect as that does not mean very much to me.

Here is a small film showing the esophageal mucosa. It looks perfectly normal to me. Here is one showing a round defect, which looks like the normal aorta and not an aneurysm. This film also shows the mucosal pattern very well in the involved area. There is no irregularity.

The films of the stomach show nothing unusual.

As far as I am able to interpret the findings, there is no evidence of an intrinsic lesion in any part of the gastrointestinal tract. The changes in the heart and great vessels are those of arteriosclerosis with tortuosity of the aorta.

DR BREED: If we may depend upon the x-ray, and I think we can in this case, we can rule out any intrinsic disease of the esophagus, any aneurysm in the thorax, and any diaphragmatic hernia.

If that was really anuria and not sphincter disturbance, with a large bladder, that is of some importance, and I take it that they probably did determine whether her bladder was full, and I have to interpret this as anuria and not a full bladder. When a patient goes into anuria suddenly in one day one is faced with some rather fantastic possibilities. We have no evidence that she had any kidney disease. We can possibly imagine a new growth obstructing both ureters, or pressing on both ureters, also a thrombosis of the abdominal aorta, with a thrombus of the renal arteries, but there is no particular evidence of that. So that we have to take that statement and not explain it very well.

I do not understand why she was in the lavatory. She had a temperature of 101°, but

she got there and fainted. No one saw her, and so we do not know whether she had pain in the terminal episode. We know nothing about it except that she died in the lavatory.

This brings me up to 10:30 last night. I awoke in the middle of the night, and something told me that this woman had a dissecting aneurysm. I said, "All right." So I took the syndrome of dissecting aneurysm and put it back over this history with the data and I must say that except for the absence of pain, it makes more sense than anything else I can think of, and the more one thinks about it the more it seems to fit the diagnosis of a slowly dissecting aneurysm. We know that she had had hypertension in the past, at least we assume she had it fourteen years previously, so she has a setting for that. We know she has arteriosclerosis. We know she does not have syphilis, that the aneurysmal symptoms, as a matter of fact, began in the throat, gradually worked down toward the abdomen. Then we come to this twenty-four hours of anuria which may be explainable on the basis of a dissecting aneurysm down the thoracic and abdominal aorta, involving the renal arteries.

In my first attack on this case I considered this diagnosis but threw it out because there was no history of real pain in the story. Of course that is the hurdle that we have to get over. We do not know how much pain she had before death, no one knows, and I can conceive of a slowly dissecting aneurysm that would not give much pain but would explain this picture better than anything I can think of.

I am going to be either very wrong or very right in this case, and I do not want you to think that this is a guess. I actually believe she did have dissecting aneurysm. She died rather suddenly. She might have had rupture into the pericardium, hemopericardium, that would account for the picture described. Shortly before her death the pulse rate was not rapid. As you know, the neck veins were distended, and—this is rather theoretical—but inasmuch as these people do die of rupture into the pericardium very often, I am going to say that I think she had a dissecting aneurysm which had got as far as the renal arteries and that her death was due to a hemopericardium.

DR T. B. MALLORY: We would welcome any other suggestions.

A PHYSICIAN: How about abdominal aneurysm in the region of the renal artery?

DR BREED: All right.

DR MALLORY: The vote is registered.

DR PAUL D. WHITE: I think the observation of engorgement of the neck veins at the time when she should have been in a state of shock is significant and backs up Dr. Breed's feeling.

that there should be something in the pericardium, possibly from a ruptured heart.

CLINICAL DIAGNOSES

Coronary heart disease

Ruptured coronary infarct with hemopericardium?

DR. WILLIAM B. BREED'S DIAGNOSES

Dissecting aortic aneurysm

Hemopericardium

ANATOMIC DIAGNOSES

Rheumatic myocarditis

Endocarditis, chronic rheumatic, with calcification of the tricuspid valve, with stenosis and calcification of the mitral valve.

Hydrothorax, bilateral

Arteriosclerosis, moderate, generalized

Diaphragmatic hernia, small.

Operative scars hysterectomy, appendectomy and bilateral salpingo oophorectomy

PATHOLOGIC DISCUSSION

DR. MALLORY Dr. Breed's explanation of the symptomatology seems very good, a little better than we actually found, however.

The autopsy was done with a good deal of care and Dr. Holmes, who was doing it, was very much perturbed because when he finished the autopsy he could find no cause of death what ever. The positive findings were extremely scant. She had a definitely old but mild mitral stenosis with calcified leaflets, but no great shortening of the chordae tendineae. The aortic valve was negative. The pericardium was negative. The aorta showed only traces of atheroma. The coronaries were capacious. He called Dr. Bradley who went over all the organs with extreme care and could find nothing else. We examined the head. The brain was absolutely normal, but I think that now having seen the microscopic sections, we have the answer to the case.

Will anyone hazard a diagnosis after that statement?

A PHYSICIAN Did the trachea and throat show anything?

DR. MALLORY The trachea and throat were negative. There was a small diaphragmatic hernia. The rest of the esophagus was negative. A few petechial hemorrhages were found in the stomach.

DR. WHITE Are you referring to the microscopic sections of any particular organ?

DR. MALLORY I will even go so far as to say the sections of the heart.

DR. WHITE Syphilitic myocarditis?

DR. MALLORY No, rheumatic.

The heart shows more Aschoff bodies per cubic millimeter than any heart I have ever

seen. I have seen one other death, in an individual in his fifties, with absolutely nothing to show for it but an acute rheumatic myocarditis with essentially negative valves. It is one of the rare possibilities of sudden death. The exact mechanism of death I think is pretty hard to guess. The most reasonable would be heart block although the symptoms of the terminal five minutes do not sound much like it.

DR. BREED What about these symptoms in relation to irritation of the esophagus trachea and various other things? They are not explained.

DR. MALLORY We found absolutely no explanation.

DR. WHITE A severe sore throat might have started it.

A PHYSICIAN Was the heart greatly dilated?

DR. MALLORY Moderately, not particularly.

DR. WHITE How much did the heart weigh?

DR. MALLORY 300 grams.

DR. WHITE Then there must have been dilatation in life. By x ray it was considerably enlarged.

A PHYSICIAN Would you have any idea how old that lesion was?

DR. MALLORY It is consistent with the duration of her symptoms, three months.

DR. BREED Of course the fact that she did not have any pain is an important feature which points away from my diagnosis.

DR. MALLORY Yes.

CASE 22042

PRESENTATION OF CASE

First Admission. A forty-one year old American dietitian was admitted complaining of cough and epotum.

The patient had whooping cough at the age of six and had coughed with varying intensity ever since. She remained fairly well, however, until the age of nine when she developed pneumonia and thereafter was always "quite delicate." At thirteen years of age she was sent to a sanatorium, where she remained six months. All tests done there were said to be negative. Her cough continued and at the age of twenty-five she contracted influenza, which confined her to bed for five weeks. Six years later she again had pneumonia, evidently lobar in type, and was ill for eight weeks. Fluid was said to have been present in the chest although it was not tapped. At thirty-nine she had another attack of influenza at which time during paroxysms of cough, she had two hemoptyses, one of which consisted of about a pint of blood. There had been blood streaked sputum for several years prior to this episode but never any gross hemoptysis. She was then sent to another sanatorium where she remained for a year and a

half and was discharged a month prior to entry here. Her cough was still present and was occasionally paroxysmal and productive of greenish sputum which was frequently noisome. She noticed wheezing sounds in the chest and for the past two years had a fairly constant pain in the left chest aggravated by deep inspiration and cough. She did not think that she had run a febrile course, and never had night sweats. Repeated examinations of sputa showed no tubercle bacilli.

The patient had migrating painful swollen joints in childhood. The details were not recalled. At one time as a child she developed numerous black and blue blotches on the skin. Two years before entry she was told that she had a leaking heart valve. An attack of measles complicated by an otitis media had left some impairment of hearing.

Physical examination showed a well-developed and nourished woman sitting quietly in bed. There was a very marked right congenital torticollis. The right chest was slightly more prominent posteriorly than the left. Expansion was limited in the lower half of both lungs. Tactile fremitus was normal. There was moderate dullness over the entire posterior chest. Bronchovesicular breath sounds were heard in the left infraclavicular region and in the entire posterior chest. Bronchial breathing was audible over the lower dorsal spine and many fine moist râles were heard in both upper paravertebral regions. The heart was not enlarged. There were no murmurs. The blood pressure was 170/105. There was slight clubbing of the fingers.

The temperature was 99°, the pulse 100. The respirations were 20.

Examination of the urine was negative. Examination of the blood showed a red cell count of 5,070,000, with a hemoglobin of 95 per cent. The white cell count was 18,000, 68 per cent polymorphonuclears. The sputum was greenish-white in color and contained no blood, tubercle bacilli or spirochetes. The stools were negative. A Hinton test was negative. Intra-dermal tests with one-tenth cubic centimeter 1:20,000 old tuberculin were negative after forty-eight hours.

X-ray examination showed mottling along the course of the lung markings to both bases. There was bilateral prominence of the hilar shadows. The right leaf of the diaphragm was somewhat irregular in outline. After lipiodol the bronchial visualization was not satisfactory although the findings were considered consistent with bilateral lower lobe bronchiectasis.

The patient was treated with postural drainage. A bronchoscopy showed diffuse congestion of the bronchial mucous membrane and a profuse secretion, the character of which was not

recorded. The patient's condition remained unchanged. The course was afebrile and she was discharged on the seventeenth day.

Second Admission, eight months later

Following her discharge the patient received a series of three x-ray treatments to the chest after which her cough and sputum increased in amount but later decreased. Thereafter her condition was unchanged for about four months, when the cough and sputum began to increase. The latter was approximately 5 to 6 ounces daily and was slightly more tenacious than previously. In a period of seven months her weight decreased from 140 to 127. There was a slight evening rise of temperature to 99.5°. For several weeks prior to reentry she became somewhat short of breath and the pain in the left side of the chest was increased in severity. For three weeks preceding her return to the hospital she had three or four loose watery stools daily. There was no melena.

Physical examination showed moderate pallor of the skin and mucous membranes. Tenderness was elicited over the frontal sinuses. The heart was considered to be at the upper limit of normal size. A presystolic rumble and a loud snapping first sound were heard at the apex. The blood pressure was 140/95. Bronchovesicular breath sounds were heard in both infraclavicular regions, and some fine moist râles were present in the lower axillae and bases posteriorly.

The temperature was 99°, the pulse 100. The respirations were 25.

Examination of the blood showed a red cell count of 5,700,000, with a hemoglobin of 90 per cent. The white cell count was 13,400, 84 per cent polymorphonuclears. The sputum contained neither spirochetes nor tubercle bacilli. The stools were semi-formed but otherwise normal.

X-ray examination showed a spread of the disease with complete collapse of the left lower lung and marked displacement of the heart to the left. The entire right lung field was mottled and showed several areas of dullness about 3 centimeters in diameter in the midlung field.

She was treated with postural drainage and a ketogenic diet with but little improvement. Ten days after entry the lower half of the left chest posteriorly showed diminished tactile fremitus with dullness to flatness upon percussion. In this region there were bronchial breath sounds, egophony, and bubbling râles. An x-ray after the injection of lipiodol showed some dilated incompletely filled bronchi in the left lower lobe. Those in the right middle and lower lobes were also dilated. There was an outpouching of the right main bronchus opposite the region of the branching of the upper lobe bronchus. Later a bronchoscopy was attempted but the patient developed marked dyspnea and cy-

anosis which persisted for eighteen hours. Thereafter, however, drainage improved slightly and she was discharged seven weeks after entry. Her temperature had fluctuated between 98° and 100° during this admission.

Final Admission, four months later

For a short time after her discharge the patient felt considerably better but in about a month she began to have increased breathlessness to such a point that even walking produced respiratory distress. Later the cough became progressively worse and more paroxysmal in character. She expectorated about two ounces of sputum daily. It no longer had a foul odor. Four weeks preceding reentry she noticed swollen ankles. This persisted and was accompanied by slight swelling of the hands. There was also tenderness in the right subcostal region and epigastrium. Shortly afterwards she began to have attacks of sharp pain and a sensation of constriction under the left breast. The pain radiated to the left shoulder and down the ulnar side of the arm. These attacks were usually precipitated by exercise and were relieved promptly by immobilization. There was also slight swelling of the abdomen and occasional small hemoptyses.

Physical examination showed a poorly nourished woman who was markedly cyanotic and dyspneic, with evidence of expiratory difficulty. There was slight exophthalmos but no other ocular muscle dysfunction. An increase in the anteroposterior diameter of the chest was noted. Both bases posteriorly up to the angles of the scapulae were flat to percussion. The remainder of the chest was hyperresonant. There were numerous coarse moist râles audible generally. The left border of cardiac dullness extended 11.5 centimeters from the midsternal line and the right border was percussed at the right sternal edge. The sounds were rapid but regular. One examiner found no murmurs or thrills, and another recorded the observation of a presystolic rumble and a snapping first sound in the mitral area. The abdomen was distended, with shifting dullness in the flanks. The liver was enlarged to percussion and tender. The spleen was not palpable. There was massive edema of the extremities up to the sacrum.

The temperature was 98°, the pulse 130. The respirations were 35.

An electrocardiogram showed sino-auricular tachycardia, a low T₁, flat T₂ and inverted T₃. P. was prominent and slightly notched. There was slight elevation of the S-T₄ take-off and an upright T₄.

X ray examination showed marked increase in all lung markings. The heart shadow was considerably increased in size, particularly on the right side and in the region of the pulmonary conus. There was believed to be some fluid present at the bases.

She was treated with diuretics and palliative

measures but her condition failed to improve. The temperature rose to 103° and tubular breathing became audible in the left lower chest posteriorly. She became progressively more dyspneic, cyanotic, and edematous, and died after being in the hospital two weeks, fourteen months after the first entry.

DIFFERENTIAL DIAGNOSIS

Dr. EDWARD F. BLAND. This lengthy clinical record may be discussed briefly. There appear to be two important aspects, namely, a long history of (1) pulmonary disease beginning with whooping cough at the age of six and ending with (2) the signs of rapidly progressive right-sided heart failure. It seems likely that the two conditions are closely related.

The important features of the pulmonary history are the frequency of acute respiratory and pulmonary infections during the earlier course followed by symptoms indicative of chronic pulmonary disease becoming worse during the last four years of the patient's life, together with clinical, x ray, and bronchoscopic evidence of extensive bilateral pulmonary disease, fibrosis, and bronchiectasis. The finding of clubbed fingers in the absence of clear evidence of congenital heart disease or of subacute bacterial endocarditis further supports the impression of important and long-standing pulmonary disease.

Tuberculosis seems unlikely in view of the clinical course, the x ray findings, the repeatedly negative sputum examinations for acid fast bacilli, and the negative tuberculin reaction. The possibility of malignant disease of the lung (either carcinoma or lymphoma) is remote. Mention is made of "three x ray treatments to the chest" following the patient's second admission to the hospital. At first glance it suggests that malignant disease was suspected. However, upon further consideration it is obvious that if this possibility had been seriously entertained more extensive exposure would have been carried out. Furthermore, a short while ago a therapeutic test with minimal exposure to roentgen rays was being tried in this hospital for various nontuberculous and nonmalignant pulmonary conditions. In the absence of positive results, it has subsequently been discontinued. I must assume that this is the explanation for the above reference to the three x ray treatments. It is reasonable to suppose then that this patient had chronic nontuberculous pulmonary infection with extensive fibrosis and bronchiectasis.

The second and more or less terminal phase of the clinical course began four months before death with the appearance of symptoms and signs of rapidly progressive heart failure which did not respond to the usual therapeutic measures. The x ray picture and the physical

signs are primarily those of right ventricular dilatation and failure. I believe we are dealing here with the so-called pulmonary type of heart disease (cor pulmonale), the result of long-standing strain primarily on the right side of the heart with ultimate hypertrophy, dilatation and failure of the right ventricle. Extensive pulmonary fibrosis is the most frequent cause, less often obliterative disease of obscure etiology involving the pulmonary arteries is responsible.

The electrocardiogram is of considerable value when cor pulmonale is suspected. We expect to find right axis deviation and its absence casts considerable doubt upon this probable diagnosis, unless there is also present some other complicating factor causing left ventricular strain also. Hypertension and aortic valve disease are the most frequent causes of left ventricular hypertrophy. No mention is made in the clinical report of axis deviation in the electrocardiogram and we have no way of knowing whether it was present. The upright T wave in lead four suggests that it may have been present.

It is of some further interest to speculate on the possibility of rheumatic heart disease and mitral stenosis. The vague rheumatic history in childhood, the discovery of an apical systolic murmur in later life, and the presence during the last admission of an inconstant presystolic rumble are of interest but do not constitute conclusive evidence of rheumatic heart disease. It may be that the inconstant diastolic rumble was a functional murmur dependent upon right ventricular dilation and comparable to a similar murmur frequently observed during severe rheumatic carditis in children. In these latter instances it has been shown recently that the diastolic rumble is dependent upon cardiac dilatation, presumably of the left ventricle. In this patient, although we cannot exclude minimal rheumatic mitral valve disease, it seems unlikely that it was an important factor in the ultimate failure of the heart. Furthermore, the last x-ray film shows considerable enlargement in the region of the right ventricle and the pulmonary conus, but no clear evidence of left auricular enlargement. This suggests that the important point of obstruction to the blood flow was not at the mitral orifice but farther back and in the pulmonary circuit itself.

A final symptom warrants further comment, namely, during the last admission to the hospital mention is made of attacks of constriction and pain under the left breast radiating to the shoulder and down the left arm and promptly relieved by "immobility." Lead four of the electrocardiogram is suggestive of coronary disease. Whether we will find evidence later at postmortem of coronary changes,

I am unable to predict. It seems unlikely that the terminal heart failure was dependent upon important coronary artery disease.

In closing then the most reasonable deductions to be made from this clinical record are that we are dealing here primarily with long-standing nontuberculous pulmonary infection, fibrosis, and bronchiectasis, and "cor pulmonale" with right ventricular hypertrophy, dilatation, and congestive failure. Although unlikely, we cannot definitely exclude the possibility of minimal mitral valve disease or of coronary artery sclerosis.

CLINICAL DIAGNOSES

Bilateral bronchiectasis
Bronchopneumonia
Rheumatic heart disease with congestive failure

DR EDWARD F. BLAND'S DIAGNOSES

Bronchiectasis, bilateral
Pulmonary fibrosis
Cor pulmonale
Mitral stenosis?
Coronary artery sclerosis?

ANATOMIC DIAGNOSES

Bronchiectasis, bilateral, lower lobes
Bronchopneumonia, diffuse, bilateral
Pulmonary edema, diffuse
Pulmonary emphysema, slight, bilateral
Pleuritis, chronic fibrous, bilateral
Pulmonary tuberculosis, healed, left apical
Rheumatic heart disease, healed, with mitral and aortic stenosis, moderate
Bacterial endocarditis, recent, mitral
Cardiac hypertrophy, right ventricular (cor pulmonale)
Mural thrombus, right auricle
Pericarditis, acute fibrinous and chronic fibrous with calcification
Chronic passive congestion of liver, spleen, and kidneys
Cholecystitis, chronic
Cholelithiasis
Calculi in cystic duct with obstruction
Peritonitis, acute generalized, ? origin
Ascites
Peripheral edema
Pulmonary osteoarthropathy, fingers
Torticollis, right
Leiomyoma uteri
Follicular cysts of ovaries

PATHOLOGIC DISCUSSION

DR TRACY B. MALLORY: Dr Bland was quite correct in his two chief diagnoses. The physicians on the ward agreed on the matter of bronchiectasis but felt that the heart condition was probably rheumatic with mitral stenosis. The

autopsy, I believe, supports both points of view. There was definite rheumatic heart disease with both mitral and tricuspid involvement. A small patch of acute endocarditis was found on the mitral valve. The right auricular appendage was filled with a firm adherent thrombus. The degree of mitral stenosis was, however, not very great and the tricuspid involvement would at most, have caused only a very slight regurgitation. The right ventricle, however, was markedly hypertrophied, measuring 10 millimeters in thickness. I should doubt if the valvular lesions were adequate to explain this, and I am inclined to agree with Dr. Bland that there was a significant element of cor pulmonale. The stabbing substernal pain which had been complained of was certainly not due to coronary disease, and since we found a slight, fresh apparently healing, fibrinous pericarditis I imagine there is little question that it was caused by that. Interestingly enough, there was evidence of a localized old area of calcified pericarditis about 3 centimeters in diameter. I am inclined to tie this up with several calcified nodules found at the apex of the left lung and assume that at one time she had an active tu-

berculosis with beginning involvement of the pericardium. This was evidently far back in the patient's history; however, since no active tuberculous lesions were discovered. The bronchiectasis was limited to the two lower lobes and was accompanied by a considerable degree of pulmonary fibrosis. The upper lobes showed a complex mixture of emphysema, diffuse edema, and localized patches of bronchopneumonia.

A complete surprise in the case was a very early generalized peritonitis. This was most marked in the left upper quadrant, just beneath the diaphragm. Although no definite sub-diaphragmatic abscess could be made out, there was evidence of some purulent infiltration of the left leaf of the diaphragm itself, and since the lower lobe of the lung was densely adherent it was felt that one of the bronchiectatic cavities had probably penetrated the diaphragm and was responsible for the beginning peritonitis.

The liver, as might be expected with such marked right-sided heart hypertrophy, showed an extreme grade of chronic passive congestion. The gallbladder contained no bile pigment and many small stones. One stone completely plugged the cystic duct.

ARE EXAMINATIONS ADEQUATE?

A STOCK objection to the introduction into the statute of the characterization of a medical school that it be "approved by the board", if its graduates are to be accepted for examination for registration is that the examination now provided by law furnishes adequate protection against incompetent practitioners of medicine. Is this assumption justified?

The wording of the statute is that the "examination shall be sufficiently thorough to test the applicant's fitness to practice medicine". The first question is whether any examination which the board can give can be adequate to test fitness for practice. The qualifications are knowing, knowing how and that peculiar quality which ensures that the physician shall do the best he knows how at all times. They may be stated in other terms as knowledge, skill and character. Which of these is most important? The qualified physician must have them all and none can be omitted. It is irrelevant, therefore, to say that one is more important than another since all are essential.

To what extent can the examination test these

three qualities? Information can be tested well. The examination can be made so long, so thorough, so rigorous, so exhaustive, that the informational content of the mind of the candidate can be adequately exposed by written and oral exercises. Skill can be brought out by confronting the candidate with situations which exhibit and test his ability in practice. But how shall character be tested? Many persons insist that character is the most important qualification for practice. Knowledge and skill grow with experience in practice; they doubt if character is improved *pari passu*.

How then can the board assure itself of the character of the candidate? It cannot assure itself by any test which will give it first-hand knowledge. Since it must depend on other persons, on whom shall it depend? Shall it depend on friends of the candidate, likely to recommend without discrimination? Shall it depend on the hospital where the candidate has had an internship? Shall it depend on the medical school where the candidate has spent four years?

It might depend on the hospital, if the internship were required before admission to the written examination, and if the hospital would make a careful study of its interns and report faithfully and honestly. This is a responsibility few hospitals are likely to assume unless identified with medical schools in preparing the candidate for his medical degree.

It is the medical school which ought to have in mind at all times throughout the four years this question: is this candidate a suitable person to be entrusted with the responsibilities of the practice of medicine? In the school also, the examinations may adequately test knowledge and skill, but only close personal contact with the student will reveal his character. Many medical schools are accepting this responsibility and consequently many state boards are depending on such schools as are meeting this responsibility well, for information as to character.

If medical schools fail in this duty, if their recommendation is found to be of little value, if it is a matter of experience that they show little discrimination in the kind of person on whom they confer degrees, their recommendation should not be accepted. It is in this respect that the nonapproved schools are seriously deficient. If the candidate can pay the tuition and can learn enough to pass the examination (often deplorably low) and conducts himself while in the school without flagrant disregard of its rules, little attention is paid to his past record or to those personal qualities without which the candidate is not a physician but a mere trader, bartering for money the health and welfare of the sick and suffering.

The character of the physician may be no more essential than his knowledge and his skill, but it is the finest flower of his years of study and discipline and cannot be tested by examination.

"CONCERNING MR MILQUETOAST"

PROBABLY since the very beginning of medicine there have been conceptions and ideas having to do with matters of health that have been more or less generally accepted by the lay public, but to which the medical profession has given little attention. The particular ideas of this kind that have been disregarded have varied from time to time according to the remoteness of their concepts to the particular aspects of scientific medicine that have been stressed at the time. The scientist has ever been averse to work in fields where he had no or very poor scientific tools with which to work and was (and is) just not interested in such things. An example was the almost universal point of view twenty-five years ago that infection was the cause of practically all ills. Now we know that the outcome of many infections is much more related to the patient's resistance than it is to the fact that a certain infection had gained a foothold on the system. Thus resistance at times is frequently connected with the diet and manner of life of the individual over a period of years preceding the infection. Since the impetus given to the scientific study of the diet that has been stimulated by the work of Minot, Sippy, Joslin and many others the knowledge in this field has grown rapidly and is probably on the threshold of much greater discoveries in the near future. For example, relationships between vitamin C (Cevitamic Acid) and the suprarenal cortex have been established thereby bringing vitamins and hormones into relationship.

Now let us go back to the sentence at the start of this editorial and consider the wide spread conception expressed by the compound word "milkop", or the similar conception recently popularized in the "funnies" concerning "Mr Milquetoast." This idea has certainly existed in the English literature for hundreds of years and indicates a feeling that the person who drinks a lot of milk is not so much of a man as the person who drinks other fluids or eats, perhaps, more red meat. Now is it scientifically possible that an excessive milk diet over a long period of time might produce a "Mr Milquetoast" in an individual who would have been a "tough guy" on some other diet? We certainly do not know this, but there is a very interesting possibility that this might be true if the newly recognized pituitary hormone, prolactin, which governs the secretion of milk is itself in some part secreted in milk. As yet no experiments have been published that show whether this is true. But consider the indirect effects of prolactin. Riddle¹ and his co-workers have shown that when an animal has been properly "primed" with injections of prolactin or theelin, injections of prolactin will change the personality of the animal to such an extent

that it will take care of a young animal that it would otherwise eat. This gives us a hormonal explanation of motherly love. From this concept it is not a far jump to the concept that possibly too much of this hormone taken in the form of food will tend to produce maternal characteristics in an individual who might otherwise be a "he-man."

WHY SHOULD PRACTITIONERS GO TO THE ANNUAL MEETING OF THE MASSACHUSETTS MEDICAL SOCIETY?

The New England Journal of Medicine will report accurately the scientific program presented at the June meeting in Springfield as well as the other medical and nonmedical problems which come up at the Council Meeting and the Annual Meeting. The representatives of the commercial houses will call at the practitioner's office and keep him posted on the new appliances that may be of use in the diagnosis, treatment and prevention of disease.

The postgraduate courses offered by the Society will bring to the practitioner's door the recent advances in medicine. With all these opportunities to keep the practitioners up-to-date, why should one spend the time and money to attend the Annual Meeting? No amount of reading (if it is done) can take the place of contact and conversation with the men who present the scientific program. The value of a man's work can be much better appreciated after one has seen and heard the individual. The broadening influence of meeting and talking with fellow practitioners must be apparent to everyone.

The scientific exhibit cannot be brought home to the individual. The practitioners will see that equipment for complete medical study exists in Springfield and will realize that there may be several centers in Massachusetts to which they may turn for consultations. Finally, the three days' vacation will be good for the practitioner's health and make him the more appreciated by his patients.

STATED MEETING OF THE COUNCIL

A STATED meeting of the Council will be held in John Ware Hall, Boston Medical Library, 8 Fenway, on Wednesday, February 5, 1936, at 12 o'clock noon

Business

- 1 Call to order at 12, noon
- 2 Reading record of last meeting in abstract
- 3 Obituaries of Councilors who have died since the last meeting
- 4 Report of Committee of Arrangements for the Annual Meeting next June
- 5 Report of Auditing Committee and of Treasurer
- 6 Reports of Committee on Membership and Finance
- 7 Reports of committees appointed to consider petitions for restoration to the privileges of fellowship and appointment of new committees
- 8 Report of Committee on Medical Education and Medical Diplomas
- 9 Appointment of three delegates and three alternates to the House of Delegates, American Medical Association, for two years from June 1, 1936
- 10 Appointment of delegate to Annual Congress of the American Medical Association on Medical Education and Licensure at the Palmer House, Chicago, February 17 and 18, 1936
- 11 Appointment of two delegates to each of the annual meetings of the five New England State Medical Societies in 1936
- 12 *Incidental Business*

ALEXANDER S BEGG,
Secretary

Boston, January 28, 1936

Councillors are asked to sign one of the two attendance books before the meeting The Cotting Luncheon will be served immediately after the meeting

EXTRAUTERINE PREGNANCY

The typical picture of an unruptured extra uterine pregnancy is about as follows. The patient skips her regular menstrual period and a few days or a week or two later begins to dribble blood, usually dark in color. Repeated attacks of severe sharp unilateral low abdominal pain occur, sometimes accompanied by fainting.

Examination at this time shows a very slightly enlarged uterus and a unilateral tender mass, which increases definitely in size if examination is repeated at intervals of two or three days. Temperature, white count, and sedimentation time are normal.

Unfortunately there are many factors which may obscure the typical picture of an ectopic pregnancy. The differential diagnosis in the main is from pelvic inflammation, cystic ovary early miscarriage and rupture of Graafian follicle with unusual bleeding.

A large percentage of tubal pregnancies are preceded by chronic pelvic inflammation, so that the new symptoms may be misinterpreted as a continuation of the previous trouble.

Cystic ovaries often cause sharp pain and by interference with the estrin progesterin balance cause irregular menstruation simulating ectopic

gestation. On the other hand, the patient may have a cystic ovary on one side and an extra uterine pregnancy on the other.

In the above conditions the Aschheim Zondek test, if one dares to wait for it, provides conclusive evidence.

An early miscarriage with severe pain may simulate extrauterine pregnancy with impending rupture, and in doubtful cases either examination and perhaps curettage must be resorted to, to clear up the diagnosis.

Rupture of Graafian follicle with undue hemorrhage may simulate tubal abortion in that the patient has an attack of severe pain, usually midway between periods with development of a tender boggy resistance in the posterior cul-de sac. Regularity of the periods and a negative Aschheim Zondek test should enable one to make the diagnosis clear.

Atypical histories are perhaps more common than typical ones in early ectopic pregnancy. Some patients have amenorrhea and no suspicion that they are otherwise than normally pregnant until rupture suddenly occurs. Less commonly, menstruation may be perfectly regular. Sometimes the slow leaking of blood into the peritoneal cavity with consequent protein decomposition and absorption may cause elevation of temperature and leucocytosis.

The most valuable points in the early diagnosis of extrauterine pregnancy are any irregularity of menstruation with intermittent attacks of pain, plus a rapidly increasing, exquisitely tender mass, with a temperature normal, or only slightly elevated, and a positive Aschheim Zondek test.

Unrecognized extrauterine pregnancy may terminate in one of three ways: first by tubal abortion, secondly by rupture, and thirdly (very rarely) development to term when so called "missed labor" occurs.

When abortion of the embryo through the fibrinated extremity of the tube occurs, there is an attack of severe pain and on examination a boggy, very tender mass of varying size localized in the pelvis may be palpated.

When rupture occurs there is a history of severe abdominal pain with faintness and the signs of internal hemorrhage: pallor, feeble pulse (not usually very rapid, however), low blood pressure and cold and clammy skin. The abdomen is slightly distended, very tender, especially on the side of the rupture and there is shifting dullness in the flanks. Vaginal examination shows a diffuse, boggy resistance and marked pelvic tenderness.

When extrauterine pregnancy develops to term there are usually vague pains suggestive of labor, followed by disappearance of fetal heart tones and movements but nothing further happens. Usually examination, under anesthesia

A series of short selected articles by members of the Section is being published weekly. Comments and questions by subscribers are solicited and will be discussed by members of the Section.

if necessary, will show the uterus of small size and distinct from the mass due to the pregnancy. It is not uncommon, however, for the diagnosis to be missed by several consultants before the correct solution of the problem is arrived at.

The treatment of extrauterine pregnancy at any stage is immediate operation. In ruptured ectopic pregnancy, however, with the patient in extreme shock, operation should be deferred until transfusion has been performed or intravenous glucose solution, heat, morphia, etc., have improved the patient's condition sufficiently to stand surgical intervention.

QUARTERLY BULLETIN OF THE BOSTON MEDICAL LIBRARY

JANUARY 1936

President

Lincoln Davis, M.D.

Vice-Presidents

Homer Gage, M.D.

Daniel F. Jones, M.D.

Elliott P. Joslin, M.D.

Secretary

James M. Faulkner, M.D.

Treasurer

Richard G. Wadsworth, M.D.

Librarian

Charles F. Panter, M.D.

Director

Mr. James F. Ballard

The purpose of this publication is to extend more widely, if possible, the service that the Boston Medical Library is in a position to render the members of the Massachusetts Medical Society particularly, and more broadly, even, the physicians of New England.

LIBRARY SERVICES

- 1 *Bibliographic* Looking up references in medical literature from original sources
- 2 *Packet Service* Pamphlets, reprints and monographs covering any medical subject from the accumulations in the Library, loaned upon request.
- 3 *Photostatic Service* Photographic reproduction of pictures, the printed page, etc.
- 4 *Library Extension Service* Monthly, regional extension books and periodicals

SERVICES

For the first three of these services and their costs, application should be made to the Director of the Boston Medical Library, 8 Fenway, Boston, Mass. The fourth service may be in-

augurated after a survey of the needs of Districts, where such service might be practicable and when plans have been worked out for defraying the costs.

It is the purpose of the Library Committee within the limits of its budget, to purchase the best of medical literature in whatever form it is presented and they will give notice in these Bulletins of such acquisitions. Citations of reviews of significant books, appearing in the columns of *The New England Journal of Medicine* and elsewhere, may serve to draw attention to authoritative information otherwise overlooked.

Physicians visiting in the City are invited to call at the Library where information is available as to what is going on at most of the Clinics, when and where Medical Society meetings are being held, the subjects to be discussed and the speakers.

The Library has for many years sought to encourage an interest among physicians in the History of Medicine and will continue to do so in these Bulletins, and in biographical sketches of noteworthy contributors to medical science, appearing in *The New England Journal of Medicine*, at other times than the regular issues of the Bulletin. During the fall and winter, the Medical History Club holds regular meetings at the Library to which all interested physicians are welcome. To render appropriate recognition of significant events in the history of medicine is one of the purposes of the History Club and the Bulletin will endeavor to call attention to these events and their celebration.

For out-of-town physicians, Members of the Library, having a little free time to while away, 8 Fenway has many interesting things to offer: the Prince Memorial Room in which one may quietly read, a Periodical Room in which are available some hundreds of the world's current medical journals, a very unusual collection of Incunabula and ancient manuscripts of great historical value, as well as numerous items of local antiquarian and historic interest and a very valuable collection of medals not duplicated anywhere else.

RULES GOVERNING THE USE OF THE LIBRARY

Hours During the months from October to June, inclusive, the Library will be open daily except Saturdays, Sundays and Holidays from 9:30 A.M. to 6 P.M. Saturdays, the Library closes at 5 P.M. From October 16 to May 31, the Library will be open Monday and Wednesday evenings from 6 to 10 o'clock. During July, August and September, the Library will close daily at 5 P.M., except on Saturdays when it will close at 12 Noon.

Most books and periodicals may be borrowed by members for periods varying from three to fourteen days.

MASSACHUSETTS LEGISLATIVE NOTES

S. 69 This bill has been introduced by Senator Miles and is a modification of that submitted last year and if enacted will relieve doctors and hospitals of the unjust burdens imposed under present conditions.

The text of the bill follows

SENATE 69

AN ACT PROVIDING SECURITY TO HOSPITALS AND PHYSICIANS IN THE ENFORCEMENT OF REASONABLE CHARGES FOR TREATMENT OF CERTAIN PERSONAL INJURY CASES

Be it enacted by the Senate and House of Representatives in General Court assembled and by the authority of the same as follows:

Chapter two hundred and fifty five of the General Laws is hereby amended by adding at the end under the heading Liens Of Hospitals And Physicians the following six new sections —

Section 40 Every registered physician, and every person maintaining within the commonwealth a hospital other than one maintained by the commonwealth or a political subdivision thereof shall have a lien upon any and all rights of action suits claims counterclaims or demands which any person treated by such physician or admitted to such hospital and receiving treatment, care and/or maintenance therein on account of personal injuries received by him as the result of the wrongful or negligent act or failure to act of any person may have, assert and or claim against such last named person such lien to be for all reasonable charges of such physician for medical and/or surgical treatment, or for all reasonable expenses and charges of such hospital at ward rates as the case may be for such treatment, care and/or maintenance of such injured person up to and including the date of payment of damages for such injury provided that a written statement containing the name and address of the injured person, if known the date upon which his injuries were sustained the name of the physician, or of the hospital or of the person maintaining the same as the case may be and his or its location or address and if known, the name and address of each person alleged to be liable to pay damages to such injured person for such injuries shall be filed in the office of the clerk of the courts (in Suffolk county in the office of the clerk of the superior court for civil business) of the county wherein such injuries were sustained prior to the payment of such damages and provided, further that such physician or such hospital or the person maintaining it, shall immediately upon filing such written statement mail postage prepaid a copy of such statement, with a record of the date and place of filing thereof endorsed thereon, to each person so alleged to be liable to pay damages whose name and address are known to the lien claimant. The claim of a registered physician made under authority of this section may

be included in, and made a part of the claim of a hospital hereunder

Section 41 The reasonable charges for which a lien under the preceding section may be claimed by a registered physician shall not exceed the charges specified for the services performed in the schedule of charges established for the county within which the lien is claimed by the Massachusetts Medical Society which is hereby authorized forthwith to establish such a schedule for each county within the commonwealth and shall file promptly a copy thereof and of all subsequent changes amendments and additions therein and thereto in the office of the clerk of the courts (in Suffolk county in the office of the clerk of the superior court for civil business) of the county wherein such schedule is or is to be effective. Before any such schedule, or any change amendment or addition therein or thereto shall become effective, a public hearing thereon shall be held by a judge of the superior court sitting within and for such county public notice of the time and place of which hearing shall be given by publishing the same at least thirty days before such date in a newspaper having a general circulation in such county. If after such hearing the judge shall be satisfied of the reasonableness and sufficiency of such charges, or of such change amendment or addition therein or thereto he shall issue an order to such effect and file the same with the clerk and thereafter in any proceeding in such county to enforce a lien established under section forty such schedule may be introduced as evidence of the reasonable value of the services so performed but in no event shall any lien be enforced for any charge in excess of such schedule

Section 42. Any lien referred to in section forty shall attach to any verdict, report, decision, decree award or final judgment or order made or rendered in any action or proceeding in any court of the commonwealth, or by any board or commission thereof, in any suit, action or other proceeding brought by such injured person or by his estate in case of his death against any person for the recovery of damages on account of such injuries as well as to the proceeds of any settlement of any such suit or of the settlement of any such claim or demand effected by any such injured person with such other person

Section 43 After the filing of the notice as provided by section forty-one no release of any judgment, claim or demand by such injured person shall be valid or effectual as against such lien and any person making any payment of damages to such injured person or to his legal representative for injuries sustained or for death caused by such injuries shall for one year from the date of such payment remain liable to the lien claimant for the amount of his or its reasonable charges due at the time of such payment in the full extent of the services and expenses to the date of such payment, and any such lien claimant may within such period enforce his or its lien by a suit at law against the person making such payment of damages

Section 44 The clerk of courts of each county (in Suffolk county the clerk of the superior court for civil business) shall at the expense of his county provide a proper docket, to be called the physician and hospital lien docket, in which, upon the filing of any lien claim under section forty-one, he shall enter the name of the injured person, the date of the accident and the name of the registered physician, or of the hospital or person maintaining the same making the claim. Such clerk shall also prepare and keep up to date a proper index of said docket, and shall be entitled to the following fees

For filing such claim _____, and at the rate of _____ cents per folio for each entry made in the lien docket and _____ cents for each search made by him in his office for a lien claim.

Section 45 Any person against whom a claim for compensation for injuries suffered by a person referred to in section forty shall be made may examine the records relative to the treatment, care and/or maintenance of such injured person made or kept by the lien claimant.

Hearing on this bill was held January 21

MISCELLANY

THE APPOINTMENT OF DR LINDE

Dr Joseph I Linde, clinical professor of pediatrics at the Yale University School of Medicine, has been appointed health officer of New Haven, succeeding Dr Leonard Greenberg, who recently resigned to become associated with the New York State Department of Labor

APPOINTMENTS AT THE CARNEY HOSPITAL

At a Meeting of the Advisory Board of Carney Hospital on January 6, 1936, the following appointments were made

Dr James P O'Hare was made Consulting Physician to the Medical Department of Carney Hospital

Dr William E Browne, for many years a member of the Surgical Staff, was appointed Surgeon-in-Chief of the Second Surgical Service of Carney Hospital

THE DRIVE AGAINST VENEREAL DISEASES

At a meeting in New York City January 15, attended by more than 2,500 representatives of the medical and nursing professions, social workers and public health officials, the problem of venereal diseases was discussed with a view to designing an efficient program for the management of this great burden on the human race

Dr Alfred Potter, Director of Dermatology and Syphilis at the Kings County Hospital, estimated that the number of cases of syphilis in the United States is 10,000,000 with 400,000 new cases developing yearly, and an annual mortality of 26,000. Comparing syphilis with other communicable diseases he cited 35,000 more reported cases of syphilis than scarlet fever, 79,000 more cases than all forms of tubercu-

losis, 500,000 more cases than of diphtheria and many more than those reported of typhoid fever

Other speakers gave statistical evidence of the new cases reported substantiating these figures

The consensus expressed by the speakers is that the remedy consists in bringing the facts out into the open. The therapy applicable to the treatment of syphilis and gonorrhea is available but the "conspiracy of silence" is thwarting the efforts of the medical profession, social hygiene programs and health departments

The solution of the problem lies in general understanding of conditions and a determined and co-ordinate movement to prevent venereal diseases

ANTI VACCINATION ACTIVITY

Members of a citizens' committee opposed to the present compulsory vaccination law held a meeting recently in Boston for the purpose of organizing a movement to secure the repeal of the mandatory provision for the vaccination of public school pupils

The proposed plan is to organize groups in various sections of the state for the development of a concerted movement to influence the Legislature to repeal the existing law. With the remarkable record of the value of vaccination in preventing smallpox, any interference with the general use of this prophylactic practice would be unfortunate

Doctors should antagonize this movement by a campaign to educate the people as to the importance of vaccination.

SERVICE RENDERED BY NEW YORK HOSPITALS

Dr S S Goldwater, Commissioner of Hospitals, New York City, is quoted in the daily papers as having said in his report for 1935 that "at least half the population of New York City depends on the city hospitals for medical care and ambulance service." This demand, Dr Goldwater explains, will necessitate the creation of new municipal hospitals in order to give that quality of service now provided in private institutions in that city. In specific details he sets forth the necessity of reducing overcrowding, tripling facilities for out patient service, laboratory extensions, larger nursing staffs, the further development of scientific research, control of clinical appointments, modernizing therapeutic equipment, closer relations with medical schools, better instruction for internes and provision for convalescents

The beds under the Commissioner's charge number 18,986 and cover long term and short term uses chronic diseases, communicable and mental illnesses

Referring to alcoholic cases the statement is made that there seems to be a substantial increase since prohibition, although in general there has been a decrease since 1916. The total days' care was 6,544,472 and the average stay was 25.1 days which is two days less than in 1934

The problems under Dr Goldwater will interest those who hold responsible positions in maintaining these institutions.

In addition to the municipal service, private hospitals of New York City accommodate about 440 000 bed patients and 1 500 000 out patients yearly. These figures show to some extent the importance of medicine in the social scheme.

The relation of medical practice in general to hospitals is being attended throughout the country. This great service to the victims of disease has an important bearing on the economics of medical practice within and outside hospital walls.

PSYCHIATRIC SERVICE AT MICHAEL REESE HOSPITAL

On January 1 1936 a Psychiatric Service in the Department of Nervous and Mental Diseases was organized at the Michael Reese Hospital Chicago, Illinois.

This service will be headed by Dr Jacob Kasanin formerly the clinical director of the Rhode Island State Hospital of Mental Diseases and lecturer in Psychiatry at Brown University and Smith College School of Social Work. Previously Dr Kasanin was connected with the Boston Psychopathic Hospital, Boston Mass. where he was the Senior Research Associate in connection with the research investigating the Social Causes for Mental Diseases under the auspices of the Rockefeller Foundation.

The Psychiatric Service at Michael Reese Hospital will have an outpatient department as well as a small number of beds in the hospital and also in the Sarah Morris Children's Memorial.

NEW YORK STATE CAMPAIGN TO CONTROL PNEUMONIA

Reduced mortality from pneumonia may be expected if plans of the Medical Society of the State of New York are successful.

In a statement issued by Dr Thomas P Farmer of Syracuse chairman of the Public Health and Medical Education Committee of the Society the campaign will be a joint project of the medical Society of the State of New York the New York State Department of Health, the State Association of Public Health Laboratories the Metropolitan Life Insurance Company and the Commonwealth Fund.

The development of the work is in direct charge of Dr Russell L Cecil of New York City chairman of the pneumonia subcommittee.

A PHYSICIAN'S FEE

In the following letter of Surgeon General Cummings to the Secretary of the Massachusetts Medical Society the information is set forth that reports of illness requested of physicians to amplify facts found in the Chronic Disease Survey will be paid for at the rate of twenty five cents.

Mirabile Dictum Twenty five cents for time consumed in the examination of records and recording facts. Even with this the likelihood of requests for more details. Official correspondence is about as voluminous as a department or bureau is able to make it.

Here is another opportunity for the long suffering doctor to serve his country with niggardly recognition by the government.

COOPERATION OF THE MEDICAL PROFESSION AND THE PUBLIC HEALTH SERVICE Treasurer Department Public Health Service Washington

December 28 1935

Dr Alexander S Begg
Secretary Massachusetts Medical Society

Dear Dr Begg

With further reference to my letter of October 15 1935 it has seemed to me that your State and local medical societies may be somewhat in doubt as to the kind of cooperation which is needed on the Chronic Disease Survey between the Public Health Service and the medical profession.

Our regional State and city supervisors have been told to get in touch with the various medical societies in their districts. I believe that in many instances this has been done but I am afraid that the explanations which have been made have not been sufficiently clear and that after the first contact the medical societies are wondering why the matter seems to be dropped especially when they read in the newspapers and hear over the radio that the survey is actually being carried on.

The principal reason for the first contact was to let the medical society know that the survey was about to start. The cooperative action between the Service and the Society will come at a later time.

The survey itself as you know is purely the collection of factual data from families. We have been very careful in the preliminary part of the survey to avoid having the lay enumerator collect medical information. The enumerator simply asks the householder what diseases have occurred in her household and records the exact words of the informant. Many such schedules will record no illness. For those that record an illness it is planned to obtain further data from the physician who treated the case. The exact method of obtaining this information has not been completely worked out. Methods are now being tested to determine which are most satisfactory. Before being applied in any area the method will be presented to the official committee of the medical society for judgment and action. Whatever the details of the method used we can say that the request for information will be mailed to the physician direct from the Surgeon General and be returned by mail to the Surgeon General where it will be treated as strictly confidential, used only for statistical analysis and will

not be returned to the local office, thus complying with the ethical standards of the medical profession. No requests for such information will go out for a month or two when a considerable part of the canvass will have been completed.

A sum has been set aside from which to pay twenty five cents for the filling out of each medical schedule.

Regional or State supervisors will visit the Secretary of the State and County Medical Society and request that the local societies designate committees to act in an advisory capacity to State and local supervisors.

Very truly yours,

H. S. CUMMING,

Surgeon General

MASSACHUSETTS DEPARTMENT OF PUBLIC HEALTH

DIVISION OF ADULT HYGIENE

Number 30 *Cancer Clinic Bulletin* January 1, 1936

The following will appear in a pamphlet issued for general distribution in the near future. A copy

of this pamphlet may be obtained by writing the Department

THE MASSACHUSETTS CANCER PROGRAM

The Cancer Program of the Department of Public Health of Massachusetts was inaugurated in 1926 by legislative enactment. According to law, there are four major activities—first, statistical research

for the evaluation of the problem secondly clinics whereby group diagnosis is made available to every individual in the State thirdly the Pondville Hospital wherein it is possible to adapt the best-known methods in diagnosis and treatment of cancer to the needs of the State and fourthly education for the dissemination of exact information concerning cancer for every individual in the State with the hope of eventually sublimating the current groundless fears and phobias

STATISTICAL STUDIES

The studies have covered the volume of the problem the existing hospital facilities in the State including the availability of radium and x-ray the medical social and economic aspects of the disease as well as such etiological findings as would be obtained by statistical analysis of death records, hospital records and home visits to cancer patients. This work is continuing and reports are made on new evidence as it is acquired.

CLINICS

The State-aided cancer clinics are administered by committees appointed by the local medical or organizations. These committees have charge of the administrative details connected with their respective clinics but in all cases they must conform with the minimum standards set by the Department. These are as follows:

(a) Group diagnosis. The group must consist of at least three men preferably surgeon pathologist, and radiologist. When any of these are not available other physicians may be substituted.

(b) Uniform records. Forms are furnished by the Department for this purpose as is also money for clerical service when needed.

(c) Social service. All cases of cancer and precancer are referred to social service for follow-up. The follow-up continues until death in the case of cancer and until removal of the lesion in the case of precancer. The State either furnishes money to help defray the expenses of the social worker or furnishes the clinic the services of a part-time social worker.

Every physician in the Commonwealth may bring or send his patient to the clinic for free consultative service with the group. If the individual case requires such diagnostic procedure as gastro-intestinal series this must be paid for by the patient if he is able to do so. If he is not able to do so, funds are available for this service.

Each case is returned to the physician who sent him to the clinic, and this physician decides whether he desires the assistance of social service in securing treatment for his patient.

The clinics must meet at least twice a month. At intervals determined by the clinic committee but in no instance less than once a year some form of teaching for the physician in the community is required. Some clinics perform this service by having consultants come to the clinics at stated intervals others have adopted the plan of having all

the physicians in the community serve on the clinic staff while still others confine their activities to having an address on cancer by some surgeon from another city.

The clinic itself is furnished the following services by the State: first, advice information and literature secondly funds for or services of social workers thirdly funds for travel of social worker fourthly funds for x-ray diagnosis for those unable to pay fifthly funds for teaching clinics sixthly funds for clerical assistance in clinics seventhly funds for postage telephone stationery etc. eighthly special clinics for the staffs of the clinics and ninthly reference of cancer cases to Pondville through social service.

The purpose of the clinics is to furnish physicians and the public group consultation service in cancer as well as to improve the knowledge of cancer among the medical profession and the laity. The group furnishes a diagnosis and outlines a plan of treatment for any person suspected of having cancer regardless of financial status. Every effort is made to have the family physician either come with his patient to the clinic or send the patient with such information as he cares to furnish. Any individual is admitted to the clinic although it is preferred to have the patients referred by physicians so that any tendency to use the cancer clinic in order to establish a diagnosis of a condition originally not suspected of being cancer may be eliminated.

PONDVILLE HOSPITAL

The Pondville Hospital with a bed capacity of 140 cares for any patient with cancer or suspected cancer of all types and stages provided that the patient has lived in Massachusetts for two out of the preceding three years and is certified for admission by a practicing physician.

The charges for individuals able to pay are \$10.50 per week. All others are hospitalized at no expense to themselves. Hospital charges to cities and towns for patients unable to pay their own fees are \$2.50 per day. No additional charge is made for service or treatment. Diagnostic services are free in the out-patient clinic while the charge for treatment is \$150.

Diagnostic, surgical, therapeutic, radium, x-ray (diagnosis and treatment) medical, and nursing services are available. An out-patient clinic for diagnosis and treatment is held on Thursday afternoons for new patients at 1 P.M. and old patients at 3 P.M.

The Pondville Hospital is located in the township of Norfolk, between Walpole and Wrentham, on the Boston Providence turnpike U. S. Route No. 1A. The hospital can be reached by the New England Transportation Company buses which leave from Park Square Boston. Patients may be visited from 2-4 and 7-8 P.M. every day.

Application blanks must be filled out by a registered physician and sent to Pondville Hospital. The applicant will be notified when he may be admitted.

Physicians are requested to send letters with their patients

Application blanks may be obtained from the Hospital, post office address Wrentham, Massachusetts, telephone Walpole 386, at 546 State House, Boston, from local overseers of the poor, or local boards of health. When practicable, a member of the Department staff will visit each case before admission.

EDUCATION

In order to carry out our instructions to disseminate knowledge to every individual in the State a Coöperative Cancer Control Committee is either established or is in the process of being established in every one of the more than 350 communities. This committee is composed of a small central group or steering committee, and a larger group contacted directly by the central committee, and finally, every individual in the community. The steering committee is composed of key people who have friendly and vital contacts with every type of group and individual represented in the community—religious, political, labor, foreign, social, fraternal, patriotic, and service. The members of this steering committee contact representatives of every club in the community. These clubs promise to have at least one meeting a year on cancer. A club does not have to have an impressive membership to become corporate in this plan. The small group of eight or twelve is an ideal size. The group, itself, determines the type of cancer talk it will have. Some groups prefer a formal talk followed by a question period while others prefer the round table discussion with the physician during which questions are asked. In any case a question period is desirable. It is at these small group conferences where an individual feels free to ask the questions about cancer where the real basic educational work is done.

The local physician is the one who is asked to be the teacher in this program because the decline or increase in early detection of cancer is entirely in his hands, because he will obtain more coöperation from his community if he knows exactly what to do in case of early symptoms and what the early symptoms are, because the local physician knows his community, and because it has always been the natural prerogative of the physician to teach.

THE NEW OPERATING ROOM OF THE MASSACHUSETTS MEMORIAL HOSPITALS

The formal opening of the operating floor in the new wing of the Massachusetts Memorial Hospitals, Harrison Avenue and Stoughton Street, was initiated with a series of four operations performed by distinguished surgeons who are prominently connected with the Hospitals and the Boston University School of Medicine.

According to the announcement of the Hospitals' superintendent, Dr. Henry M. Pollock, three former chiefs of the surgical service participated in programs, Dr. J. Emmons Briggs, and Dr. Charles T. Howard, both professors emeriti of surgery in Boston University's school of medicine, and Dr. Ralph C. Wiggin, who is chief of the genito-urinary surgery department of the school.

Dr. Howard M. Clute, who was recently appointed chief of the Hospitals' surgical service and professor of surgery at Boston University, was included in the group. There are four regular operating rooms, another for orthopedic work, and a sixth for obstetrical cases.

Unique among modern hospitals, the recently completed new wing at the Massachusetts Memorial Hospitals, incorporates in its plans, many novel and essentially scientific devices. Members of the Hospitals' board of trustees and other distinguished guests who had been invited on the necessarily limited list observed the operations from a balcony above the operating room proper. Benches which have flat desks before them are provided for the purpose of making notes. Guests gazed through glass partitions at the operating scene below. Shut out from the operating room itself, so that no contaminating germs may drift into the sterilized area, and no bothersome visitors will be in the way of the work at hand, the observers can listen to the voice of the surgeon explaining as he proceeds with the operation. A loud speaker microphone system will make these explana-

tions more audible than if the listener were posted beside the physician

Remembering that these balconies above the operating rooms have been designed primarily for the education of medical students Dr Pollock had built into the walls, a tube connecting balcony and operating room. The inquiring student with a question will write it out on a piece of paper put it in the carrier slip it into the tube an attendant will see it below and read it to the operating surgeon who in turn will answer for the benefit, not only of the one student with whom the question originated but for all the spectators.

Constant temperature chambers for solutions and the warming of blankets simplify this ever present problem. In the large preparation room arrangements for the making and putting up of dressings mean that only the workers in these rooms are in contact with the materials. As soon as the dressings are ready, they are put on shelves or racks and pushed into a wall container which is opened from the hall side. Thus they are not touched by other than the sterile hands which prepared them. Nor are these workers on the dressings in contact with the world outside of their own rooms, as no one is allowed inside.

The operating rooms are equipped with the most modern lighting systems. Giving the effect of daylight, the high powered lamp provides at all times a shadowless blaze of illumination. It is adjustable in all directions. Thus from whatever angle the surgeon may be compelled to work the light is always clear strong and he is never in his own shadow. The operating floor is air conditioned as to temperature and humidity. The electric switches and other fixtures are all protected to prevent sparking with resultant explosions. A double supply of electrical power to all fixtures has been arranged. Thus, in case of the failure of power on the regular lines without a winking of the lights even the other power will come on and the operating may continue uninterrupted. Apparatus is installed so that each room has air pressure and suction. By the arrangement of elevators in the new wing the patient will be moved directly from there to the operating room not having to be transported through any part of any corridor in the building.

A lounge room, comfortably appointed for the surgeons will be a popular place with the staff and a waiting room for the medical students will be the latter's headquarters when off duty. A lighted number flashing on in a glass panel on the wall will indicate to the waiting students which operating rooms they are expected to attend.

CONNECTICUT NEWS ITEMS

At the Annual Meeting of the Voting Staff of the Hartford Hospital held December 4, 1935 Dr E. R. Lampson and Dr H. G. Jarvis were reelected President and Vice-President, respectively for the ensuing year and Dr James R. Miller was elected secretary.

The Hartford Medical Society held its annual meeting on January 6, 1936. The following members were elected to office:

Edward A. Deming, President
Henry F. Stoll, Vice-President
J. Tyree Woodson, Secretary
Louis P. Hastings, Assistant Secretary
Franklin L. Lawton, Treasurer
Walter R. Steiner, Librarian
Ernest Coulfield, Assistant Librarian
C. Brewster Brainard, Alfred M. Rowley, E. Terry Smith, Trustees for one year
Stanley B. Weld, Executive Committee for 3 years

PUBLIC HEALTH IN HARTFORD

Hartford, Connecticut, with its population of 164,072 has as yet no regularly appointed health officer the position being filled until April 1 by Dr Thomas F. O'Brien, acting health officer. The health program of this city as it exists today is considered by many as entirely inadequate. In a radio broadcast on January 7 Dr C. Brewster Brainard, chairman of the joint committee of the Council of Social Agencies and the Hartford Chamber of Commerce urged that there be appointed a city health officer who would be the administrator of the Department of Health not subordinate to a Board of Health composed of citizens none of whom have been trained in public health work. Dr Brainard briefly referred to the Health Conservation contests sponsored by the Chamber of Commerce of the United States and the American Public Health Association and inaugurated in 1929. In 1934, 214 cities took part, representing over 33 million people. There were 29 cities in Hartford's population class of 100,000 to 250,000. Hartford has competed each year beginning in 1930 and never ranked lower than fourth. In 1933 it was the winning city.

In spite of its high rating Dr Brainard emphasized the point that Hartford should make a better showing in the reduction of its infant mortality record its house visits to school children and in the hospitalization of incipient cases of tuberculosis. Educational work relative to the prevention of cancer, heart disease, and communicable diseases is very inadequate. He quoted Dr Ira V. Hiscock, professor of public health at Yale who made an exhaustive study of Hartford's health guidance agencies and problems to the effect that there is lacking a coordinated, comprehensive public health education program in this city. This program might include more information concerning the importance of early diagnosis and prompt treatment of cancer, the significance of measles and whooping cough, the need for periodic medical checkup of convalescents, the prevention and care of heart disease, the problems of social hygiene, the value of a well rounded community health program and the importance of a trained personnel. Much of the credit for the public health program in Hartford has been due not

to the Board of Health, but to nonofficial agencies as the Hartford Tuberculosis and Public Health Society, the Visiting Nurse Association, and the Hartford Dispensary

It is a striking fact that in 1934 less than one per cent of the city budget was devoted to the Department of Health. The total expenditure for public health activities for that year amounted to \$2 20 per capita, but of this the city paid less than one-fourth, while the greater part was contributed by private agencies. Hartford's program of public health lacks many things, yet it is spending \$2 20 per capita, which is well within the range of \$2 00 to \$2 50 estimated as all that is required to purchase a complete public health program.

Hartford needs a trained personnel to carry on its public health work. This means a city health department 'under the direction of a health officer who is a physician especially equipped by training and experience for administrative health work and who should at least meet the requirements set up by the Conference of State and Territorial Health Officers. He should be the actual administrator of his department of the city government and not subordinate to a group called the Board of Health that is and always has been since the city was incorporated composed of citizens none of whom have been trained in public health work. The health officer should select his trained medical assistants, public health nurses, sanitary officers and clerks and should be secure against political interference or dismissal during competent performance."

All this will necessitate a change in the city charter, the same as has been done in several Connecticut cities

CORRESPONDENCE

A DISCUSSION OF DR DONALD S KING'S CRITICISM

December 30, 1935

Editor, *New England Journal of Medicine*,

I have read with interest and appreciation the excellent criticism by Dr Donald S King, in the current issue of the *Journal*, of the paper "Diathermy in Lobar Pneumonia" by Drs Resnik, Foley, and myself, which appeared in the *Journal* of October 24, 1935, on page 796

On my own behalf, as well as that of my colleagues, I should like to make some reply, especially in view of the fact that Dr King's letter may be read by some who did not read our paper

In regard to Dr King's Point 1 (dealing with pneumococcus antiserum) We wrote "we do not imply that serum, for instance, has no value, even in our present small series of cases several patients seemed to improve markedly after receiving it, the fact remains, however, that in any large series of cases, the mortality is about what it was before serum was used" If we had written "in any large series, of

unselected type, etc", which we considered would be assumed from the context, our meaning might have been clearer. We were not attempting to evaluate serum therapy, but to point out that the mortality of pneumonia, all types considered, has changed but little during the past generation

Point 2 (dealing with the debatable question as to whether or not the lung is heated by diathermy) I am referring to Dr Resnik, the physiotherapist of the group, for anything he may care to say on the subject, or on any other subject in connection with Dr King's letter

With Point 3A we are in complete accord

Point 3B brings up the question as to our method of selecting patients for each group. As in most hospital services, we had to take patients as they came in, and they did so at very irregular intervals. In addition, and as explained in our paper, there were admissions just before week ends and holidays, and at other times when the giving of diathermy would have had to be delayed or interrupted, these patients, therefore, were placed in the control group, other upsets occurred when patients were moribund on admission, also as mentioned in our paper. The discrepancy in the dates does exist, nevertheless, our series were composed as nearly as possible of alternate cases, and it was due to mechanical difficulties rather than to any "selection" for other reasons that they were not entirely so. The "selection" thus is more apparent than real, and although as Dr King points out, it does cause the time element to enter into it, we felt that this was the fairest method we could use under the circumstances

Points 3C and 3D are likewise perfectly fair in their criticism. We can only say that, as described under "Selection of Patients" in the paper, no factors such as age, condition, type of organism, and the like were taken into consideration, and that the attempt was made to select as nearly as possible one of alternate cases

We agree with Dr King that there is need for a larger series of cases before coming to any definite conclusions in regard to the use of diathermy, that, in fact, was stated several times in the paper. Thus, "From our present series it is hardly possible to draw any definite conclusions. The number of cases is so small that statistics especially must be regarded with suspicion, and we feel that our results are suggestive rather than conclusive. We feel justified in continuing with this form of treatment until a sufficiently large series of cases, with controls, has been accumulated, and more definite conclusions may be drawn. It (diathermy) appears to lower the mortality, although the present series of cases is too small to permit drawing any definite conclusions in this respect." Our article was a preliminary report, and so subtitled

Finally we wish to thank Dr King for his letter of excellent and just criticism. It was one of our hopes in writing the paper that it might arouse comment and discussion, and such constructive crit-

icism is most welcome. We are writing this reply not in any attempt to refute any of Dr King's statements, but to clarify matters for any who may have read his letter and not our paper and who may be interested in the subject.

Sincerely yours

WINTHROP WETTERDEZ, JR. M.D.

Boston, Mass

UNPAID BILLS OF DOCTORS AND HOSPITALS

Editor *New England Journal of Medicine*

The old Chronic Disease of Neglecting and Refusing to pay physicians and hospitals for services rendered in accident cases and for which the bills of physicians and hospitals were taken care of in the settlements by the insurance companies has again reached an acute condition

The Norfolk District committee arranged for personal conferences recently with the director of the insurance companies in Boston to ascertain the attitude of these companies toward House Bill 1109 introduced by H. M. Landesman M.D., last year. This Bill was recommended to Massachusetts by Dr William C Woodward Legal Adviser of the American Medical Association and was based on the now existing Lien law in Nebraska, which is apparently working out successfully. This petition, with modifications to eliminate honest and serious objections by the insurance companies and yet to protect physicians and hospitals, has been again introduced.

The directors of the insurance companies were all agreed that an injustice was being perpetrated upon the physicians and hospitals in certain cases which almost bordered on larceny by some lawyers and patients and were very agreeable to the suggestion of the medical committee member to get together at a friendly conference to see whether some gentleman's agreement could be worked out to protect the physicians and hospitals and aid them as far as possible in collecting for services rendered.

Friday January 10 1936 was the day set for this conference. The following were invited

Mr P W Linscott, Employers Liability Assurance Corp., Ltd. Mr James Holland Liberty Mutual Insurance Company Mr Martin L Hines Travelers Insurance Company Mr Arthur V Sullivan General American Indemnity Insurance Company Mr Benjamin Brooks American Mutual Liability Insurance Company Mr John W Cronin Counsel for the Liberty Mutual Insurance Company Mr R. J. Dunn, Lumbermens Mutual Casualty Company Mr John W Downs Counsel from the Insurance section Dr Joseph B. Howland Supt., Peter Bent Brigham Hospital Dr Nathaniel W Faxon Supt., Massachusetts General Hospital Dr Henry M Pnlock, Supt. Massachusetts Memorial Hospitals Dr Charles F. Willinsky Supt. Beth Israel Hospital, from the Hospital group Dr Charles E. Mongan, President, Massachusetts Medical Society Dr A. S. Begg

Secretary Massachusetts Medical Society Dr Chaunting Frothingham Suffolk District Medical Society Dr David C Dow Sr Middlesex South District Medical Society and Dr Henry M. Landesman Norfolk District Medical Society comprising the Medical group

The chairman made the following introductory remarks

Gentlemen

We have come here today for the purpose of bringing about a more amicable association. There has existed an inharmonious and a distrustful feeling among us for no good reason for we come in close contact with each other in our daily professional life. It is absolutely necessary that our business intercourse should be carried on in an honorable and friendly way for we all suffer otherwise.

You are all aware of the fact that physicians and hospitals lose tremendous sums of money annually in accident work. The sad and grievous part of the story is that moneys have been set aside by your insurance companies to pay for the medical and surgical services rendered, but these moneys too frequently are not distributed to physicians and hospitals due to some dishonest patient or lawyer. This practice is becoming worse and must be halted either by legal methods or healthy and friendly relations between insurance companies, and physicians and hospitals. The latter procedure may be the wiser.

It is not necessary to burden you and take up time to cite a series of cases in which substantial settlements were made and yet physician and hospital were not paid for their services of the highest type and efficiency. Perhaps a few cases may better be cited

1. Aeroplane accident — patient injured almost beyond likelihood of recovery. Treated by a Boston surgeon. An unlooked for excellent result was obtained. Patient got well case was settled without a lawyer for a very large sum. Patient was to pay physician, but disappeared after cashing the check.

2. Automobile accident — Mrs M C — patient struck by car traveling 40 miles per hour. Case was settled for \$2500 lawyer accepted \$1000 Patient received \$1500 and was to pay her medical expenses. She refused to pay and suit was brought. Judgment rendered by court for \$110 full amount of bill. Patient again refused to pay judgment, patient brought before Poor Debtors court. Patient appeared in old clothes and told judge that those were her only earthly possessions. He let her go.

3. Patient, A. K., injured in automobile accident in hospital a month. Case was settled a few months later for \$400. This fact was found out about six months later. Lawyer took \$260 and patient was told that the lawyer would pay the hospital and physician. A release shown by the lawyer read that the patient received \$260 (this the patient denied and made affidavit) and was to pay medical and hospital bills. Bar Association claimed that it could do nothing about it.

Hundreds of such cases could be presented here, it would take time so we will dispense with them. You can prevent the above, are you willing?

The chairman then presented what he thought and knew from his experience and study of all sides of the question, a pamphlet containing the requests by insurance companies and requests by the physicians and hospitals

REQUESTS BY INSURANCE COMPANIES (A)

- 1 That physician and/or hospital notify insurance companies early of accident case under treatment
- 2 That honest diagnosis be given to investigator, and probable prognosis
- 3 That early arrangement be made for company examination of patient
- 4 That reasonable bills be rendered for services
- 5 That physicians and/or hospitals discourage and refuse to accept fake cases
- 6 That physicians and/or hospitals refuse to deal with ambulance chasers
- 7 That physicians and/or hospitals should reply promptly on notification of prospective settlement by insurance company and answer to questions of procedure physicians and/or hospitals wish to take in cases of doubtful or no liability

REQUESTS BY PHYSICIANS AND HOSPITALS (B)

- 1 That check or draft be mailed to physician and/or hospital on same day as patient receives his draft in cases of substantial settlement
- 2 That in cases where liability is doubtful but insurance company is willing to offer some sum for settlement, if, after deduction of lawyer's fee and bills of physician and/or hospital, nothing remains for patient, physician and/or hospital should be seen by patient and a definite agreement be brought about, and company notified by patient, physician and/or hospital on the final agreement
- 3 That in case disagreement between physician and/or hospital takes place with patient, settlement need not be held up, case may be settled, but above allowed time to attach amount, if so desired
- 4 That in case where there is no liability and insurance company wishes to rid itself of same by offering a pest amount, insurance company should notify physician and/or hospital that such are the circumstances

The meeting was opened for discussion.

Dr Howland discussed the New Jersey bill of five years ago and said that he was instrumental in its introduction. He said that it went to a third hearing but was finally defeated.

Dr Pollock inquired whether the objection by the insurance companies of the constitutionality of the bill was correct. The chairman replied that according to the Legal Adviser, Dr Woodward, of the American Medical Association, the bill was constitutional.

Mr Downs claimed that the insurance companies, as far as he knew, never doubted the constitutionality of the bill, and said he did not see how we

could get anywhere because the physicians and hospitals would get special preferences by their liens even ahead of the injured man and the lawyer. For instance, in Section 1 of B, the insurance companies cannot agree in all cases to mail checks or drafts to physicians when cases are settled. They cannot quite agree to Section 2, under B, and in Section 3, insurance companies can sometimes settle a case in a day or two after an accident so they cannot agree to that, but he did feel that perhaps something can be done. Mr Downs continued, that whenever he is counsel for an injured person he always tries to send checks to physicians and hospitals directly. Of course he cannot do that in every case.

Mr Linscott said that they tried to take care of physicians and hospitals at all times possible, and he felt that some plan could be worked out to cover the abuses.

Dr Baker of the Massachusetts General Hospital said in part that emergency cases were sent to the ward after treatment, and then at the request of the patient, he would be moved to a semi-private room.

Mr Hines was of the opinion that there was an injustice done to physicians and hospitals at the expense of the insurance companies who were really not to blame, and he, too, felt that a remedy could be prepared to eliminate the loss to physicians and hospitals.

Mr Cronin felt that something could be accomplished. The case is not only a medical pay problem but involves a great deal more. The lien law refers to cases where "it is solely by fault of the other party." Many cases are settled to avoid suit where the other party is not to blame. Then again let us see the effect of the lien on another type of case. In this case, lawyer brought suit for \$2000. Insurance company felt that it was willing to pay \$800 in settlement including all expenses. There were bills of physicians and hospital for \$500. The patient was willing to take \$800 if the insurance company paid the hospital and medical bills. Without a lien law, the insurance company could settle the above case, but with a lien law, it would cost the insurance company at least \$1300 out of court. This would be a handicap to insurance companies. After discussing this matter in his office with Dr Landesman, at length, he feels that the insurance companies and the physicians and hospitals can get together on some agreement to eliminate the abuses. He cited another case of an injury to a woman's shin to show how inconsistent and ridiculous some patients can be. This woman was hit on the shin, and because she could not go away to the beach that summer, she spent \$70 for awnings for the house. She and her husband were trying to save every dollar they could to invest in stocks. Their investments brought them about 700 per cent. She also had an old colitis of many years back and this flared up again. Now she felt that the insurance company should pay her for all those conditions. Of course, this sounds ridiculous, but it is fact.

Mr Cronin suggested the following plan which

could be of use; That when a physician begins to treat a patient, if he has the patient make out an affidavit to insurance company and attorney which authorizes them to pay physician and hospital when settlement takes place, the insurance company could probably do so. He also said that the Liberty Mutual Insurance Company has always tried to take care of physicians whenever possible.

Mr Sullivan mentioned a case that the lien law might have prevented settling. Patient was badly injured and the medical and surgical bills amounted to about \$1700, case was settled for \$2500. He asked the chairman how he felt about this case and Dr Landesman replied that physicians and hospitals have always been very decent and not money mad and in a case like that if the patient was crippled, they would reduce their bills to help the patient. Mr Sullivan felt that the case could not have been settled if there was a lien law and said there were many other cases in which the bills of physicians and hospitals would actually prevent early settlement of cases.

Mr Ring of the Lumbermens Mutual Insurance Company said that this company always tries to take care of physicians and hospitals whenever possible.

Mr Britten of the American Mutual Liability Insurance Company felt that Mr Cronin had covered the subject quite thoroughly and there wasn't much more he could say except that he also felt that some definite, workable plan could be adopted.

Dr Mongen said that he was at the conference in the capacity of a general practitioner and would not discuss the lien bill. The doctors hope to work out something worth while any workable plan is worth while.

Mr Downs then asked whether Dr Miles bill would also be withdrawn in case of an agreement upon a plan. The chairman advised Mr Downs that as soon as an agreement could be arranged, he would withdraw his bill and since the hospitals and physicians were satisfied with the plan adopted, Dr Miles would likewise withdraw his bill.

Dr Pollock said that the present system is very unfair to hospitals and physicians that a committee of three should be appointed to formulate some definite plan and physicians, hospitals and insurance companies be represented.

The chairman felt that three men would not be sufficient to cover the situation, for there were three types of insurance companies: mutual groups, bureau groups, and non-bureau groups. The chairman asked the insurance company members whether it would not be advisable to have each of these groups represented and they all felt that that would be the best plan.

It was then decided that another meeting be arranged for as soon as possible on account of the pending bills in the Legislature, and that a representative from each group be chosen for the next Conference at which time a definite plan could be worked out. This meeting has already been held.

H. M. LANDESMAN M.D., Chairman

EXAMINATION FOR POSITION IN NEW YORK

January 14 1936

Editor, *New England Journal of Medicine*

This Commission is soon to proceed with an examination for the important position of Assistant Director of the Bureau of Health Education at \$5500 per annum in the New York City Health Department.

The success of this examination depends in a great measure upon the number of well-qualified persons who compete therein. May we have your personal assistance and cooperation in bringing this examination to the attention of qualified candidates?

The dates for the receipt of applications have been extended from January 14 to February 11 1936

WM. H. ALLEN, Secretary

Municipal Civil Service Commission,
Municipal Building Manhattan,
Centre and Chambers Streets,
Fourteenth Floor

THE AMERICAN PSYCHOANALYTIC ASSOCIATION

January 15 1936

Editor, *New England Journal of Medicine*,

I have the honor to inform you that The American Psychoanalytic Association founded in 1910 met in Boston December 28 at which time it adopted a new constitution. The American Psychoanalytic Association now a Federation of the American Psychoanalytic Societies has as its membership the Boston Psychoanalytic Society the Chicago Psychoanalytic Society the New York Psychoanalytic Society and the Washington-Baltimore Psychoanalytic Society.

The following officers were elected: Honorary President, A. A. Brill, M.D. (New York); President, C. P. Oberndorf, M.D. (New York); Vice-President, Isador H. Coriat, M.D. (Boston); Secretary, Ernest E. Hadley, M.D. (Washington, D. C.); and Treasurer, Leo H. Bartemeier, M.D. (Detroit).

The scientific program consisted of papers on titled:

"Humor and Hypomania" by Isador H. Coriat, M.D.
"A Contribution to the Psychogenesis of Migraine" by Frieda Fromm-Reichmann, M.D.

"The Omission of Grief: Contributions to the Psychology of Effects" by Helene Deutsch, M.D.

"Envy of the Mother and the Wish to Take from Her" by Catherine L. Bacon, M.D.

"Psychoanalytic Aspects of Some Gynecological Disorders" by Karl Menninger, M.D.

"A Case of Compulsive Masturbation" by John A. P. Millet, M.D.

Sincerely yours,

ERNEST E. HADLEY, Secretary

RECENT DEATH

MAHONEY—FRANCIS X. MAHONEY, M.D., for more than twenty years health commissioner of Boston

died on January 14, at the Deaconess Hospital, after an illness of several weeks. He was sixty four years old.

Born in Boston, Dr. Mahoney attended Boston College and Holy Cross, receiving his degree in medicine from Harvard University. He was appointed to the board of health in 1910 by Mayor John F. Fitzgerald, becoming head of the department in 1914, and continuing in that capacity until his death, except during the administration of Mayor Peters.

His long and eminent service in the health department witnessed striking reductions in infant mortality, typhoid fever and diphtheria, and the establishment of the health units in various sections through the income of the George Robert White Fund.

Dr. Mahoney was a member of the American Medical Association, the Massachusetts Medical Society, the American Public Health Association, the Massachusetts Association of Boards of Health, the Harvard Club of Boston, the Elks, Foresters, and New England Pilgrim Fathers. He is survived by his widow, and two brothers, Lt. George Mahoney of the Boston police force, and John Mahoney, chief food inspector of the health department.

NOTICES

WORCESTER CANCER CLINIC

COÖPERATING WITH THE MASSACHUSETTS DEPARTMENT
OF PUBLIC HEALTH

The Diagnostic Cancer Clinic will be held each Wednesday at 11 A.M. at Memorial Hospital Out-Patient Building.

A group of physicians who are specialists in particular fields will be present at each clinic and careful reports will be sent to the referring doctors.

ERNEST L. HUNT, M.D., *Chairman*

MEDICAL CLINIC AND STAFF ROUNDS AT THE PETER BENT BRIGHAM HOSPITAL

At 3 30 P.M. on Thursday, January 30, in the Amphitheatre of the Peter Bent Brigham Hospital, Dr. Henry A. Christian, Physician-in-Chief, Hersey Professor of the Theory and Practice of Physic in the Harvard Medical School, will give a medical clinic. To it are cordially invited practitioners and medical students.

On Saturdays in the wards of the Peter Bent Brigham Hospital, from 10 to 12, staff rounds will be conducted by Dr. Christian.

REPORTS AND NOTICES OF MEETINGS

NEW ENGLAND HEART ASSOCIATION

The November meeting of the New England Heart Association was held at the Boston City Hospital on the evening of November 25.

Dr. Samuel A. Levine opened the meeting with a

short address and then turned it over to Dr. Soma Weiss who presented the first of a series of interesting and instructive papers. His subject was a "Demonstration of Pathological Specimens." The first specimen was a heart from a case of rheumatic heart disease in which there was a very extensive stenosis of the mitral valve and a marked "fish mouth" appearance. A dissecting aortic aneurysm was then shown, remarkable in that it had ruptured back into the aorta, thus establishing two main vessels in that region. A fairly strong wall had been formed for the new passage and the patient lived for about a year after the acute episode, at which time he had had epigastric pain with cardiac failure. Two specimens from cases of bicuspid aortic valves were shown, in one of which there was a terminal history of subacute bacterial endocarditis.

In the other case there were extensive partially calcified vegetations on the valve leaflets and Dr. Weiss felt that this might represent an old healed subacute bacterial endocarditis. Congenital bicuspid aortic valves usually give no murmurs unless subacute bacterial endocarditis is present. The fourth demonstration was of two unusual congenital malformations, one with constriction of the pulmonary conus and a communication just above the intraventricular septum, the other with four leaflets in the pulmonary valve. The last specimen was from a case of subacute bacterial endocarditis in which there were vegetations in both the right and left sides of the heart. In life there had been a loud double murmur in the pulmonary area.

The subject of the second paper of the evening was "Amyloid Heart" and was delivered by Dr. Kenneth Mallory. In about 24 per cent of cases of chronic pulmonary tuberculosis there is some amyloid deposited within the heart musculature as well as in other organs, but this is not extensive enough to cause heart failure. A second type involves the tongue, heart, and smooth muscle of the gastrointestinal tract. Ten cases of this type have been reported and three of these died of cardiac failure, but no such cases were found in the pathological records of the Boston City Hospital. There is also a third group in which the amyloid is found only in the heart musculature, and there have been four such cases recorded in the Boston City Hospital. These cases were described in detail by Dr. Mallory and he showed several lantern slides to demonstrate the histopathology. There may be a focal or diffuse amyloid infiltration and in one case the infiltration was in the intraventricular septum alone and caused Stokes-Adams attacks with heart block. Dr. Mallory concluded with the statement that amyloid disease of the heart, either primary or secondary, may contribute to or even cause cardiac failure.

Dr. L. B. Ellis spoke on the "Mechanism and Treatment of Postural Hypotension." The normal adaptation to the upright position is chiefly carried

out by peripheral vasoconstriction which maintains the blood pressure. In certain conditions this adaptation is not adequate and the systolic pressure falls and syncope results. In the majority of cases this is not due to a failure of the vasomotor reflex but rather to deficient tone of the skeletal or vascular musculature leading to pooling of blood in the periphery. The mechanism of postural hypotension however is different. Here there is a failure of the vasomotor reflex to operate. In cases of this condition there is a marked fall in the systolic and diastolic blood pressures and the rate of the heart may not change at all on assuming the upright position. Although only twenty-six cases of this condition have been reported in the literature in the last two years six cases have been seen in the Boston City Hospital indicating that the condition is probably more common than has been believed. A careful study of two of these cases showed the total blood flow and cardiac output to be essentially normal when standing in spite of the drop in blood pressure.

There are multiple causes for this failure of the vasomotor reflex. The condition is not infrequently associated with disease of the central nervous system and four of the six Boston City Hospital cases had such disease two cases of tabes dorsalis one of syringomyelia and one of transection of the spinal cord. A study of the postural blood pressure reflex in cases of combined system disease and tabes dorsalis showed little that was abnormal in the first group but ten of the seventeen cases with tabes dorsalis showed an unusual drop in the systolic or diastolic pressures on assuming the upright position. One of the cases showed amyloid disease of the cortex of the adrenals and some of the cases in the literature had Addison's disease.

Treatment of postural hypotension consists of the following first, the treatment of the underlying cause where that is possible secondly mechanical measures such as bandaging the legs and thirdly drugs, the most important of which is ephedrine sulphate in doses of three-eighths of a grain three or four times a day. Although ephedrine usually relieves the symptoms it frequently does not change the abnormal fall in pressure.

"The Significance of Precordial Leads in Cardiac Infarction" was the subject of a paper by Dr. James M. Faulkner. The evolution of characteristic electrocardiographic patterns following acute cardiac infarction was illustrated graphically. In fifty-one cases with electrocardiograms characteristic of infarction, the changes were present only in the precordial lead throughout. Correlation of electrocardiographic signs with the particular coronary arteries occluded was better than with the site of the infarct as designated by the anterior or "posterior" wall of the left ventricle. It was suggested that the terms "anterior" and "posterior" were unsatisfactory for this purpose because the heart was not fixed but liable to rotation on its longitudinal

axis. In discussion Dr. Paul White suggested that the terms "apical" and "basal" be substituted for anterior and posterior respectively as more accurately expressing the location of the infarct which give the two distinct types of electrocardiograms.

Dr. Some Weiss spoke on "Recent Observations on the Functional Properties of the Vascular System and on the Hemodynamics in Arterial Hypertension." In primary hypertension, although the pressure within the arteries and arterioles is above normal that of the capillaries and veins is not increased. This suggests that the arterial hypertension is a readjustment to an increased peripheral resistance. The hemodynamics of this problem have been reinvestigated recently at the Boston City Hospital and it has been found that the cardiac output, blood volume and velocity of flow are all normal even when the pulse pressure is high. Therefore the blood supply to the tissues is not increased.

Dr. Myron Prinzmetal then discussed "The Nature of the Peripheral Resistance in Arterial Hypertension with Special Reference to the Vasomotor System." In the investigations at the Boston City Hospital the blood flow through the tissues of the arm in patients with arterial hypertension and in normal subjects has been found to be about the same. Since the head of pressure forcing the blood through the vascular bed is greater in hypertensive cases, the peripheral resistance must be greater than normal when the blood flow is the same. This indicates that the increase in peripheral resistance in arterial hypertension is general and not localized to the splanchnic area. By studying the tissue blood flow before and after the arm had been put into hot water it was found that the increase in flow was normal in hypertensive subjects, suggesting that there are no obstructing organic changes in the arm vessels of the hypertensive. Direct blocking of the vasomotor nerves to the arm by novocaine injection led to the same increase in flow in both normals and hypertensives. This indicates that the increased peripheral resistance in arterial hypertension is not vasomotor but must be intrinsic in the vessels themselves, and for this reason the common surgical procedures for the relief of hypertension do not appear logical. Four cases of coarctation of the aorta were studied in a similar way and a definite increase of four times the normal increase in blood flow through the arm was found after novocaine block so that the arterial hypertension in the upper extremities in coarctation is felt to be a physiological compensation, vasomotor in origin.

Dr. McGlantz read Dr. M. S. Segal's paper on "The Electrocardiogram in Bacterial Endocarditis as Contrasted with Rheumatic Carditis." In a comparative study of the irregularities occurring in these two conditions as seen in cases at the Boston City Hospital between 1900 and 1934 mitral

fibrillation had an incidence of forty-eight per cent in rheumatic heart disease and only two per cent in subacute bacterial endocarditis. Flutter was also much less frequent in subacute endocarditis. There was a prolonged conduction time in thirty seven per cent of the rheumatic carditis cases, and this occurred in only seven per cent of the cases of subacute endocarditis. The same is true of gallop rhythm and premature beats.

Dr R. W. Wilkins presented a paper on "The Significance of Differential Venous Pressure Measurements" by Dr E. B. Ferris, Jr. A simple apparatus for determining venous pressures was demonstrated. Femoral venous puncture for this and other purposes is simple and at times is the only method of administering intravenous therapy or of withdrawing blood without resorting to surgery. The femoral vein lies about one centimeter medial to the artery at a depth of about two and one-half centimeters in the femoral triangle. Venous pressure is normally four to ten centimeters of water and anything above twelve is abnormal. Pressure in the femoral vein represents the pressure in the inferior vena cava, that in the antecubital veins represents pressure in the superior vena cava. One or both may be elevated unilaterally or bilaterally, and the combined measurement offers an excellent method of localization. Mediastinitis, with fibrosis or mediastinal tumor, often causes superior vena cava obstruction. Ascites may cause a femoral pressure of 40 to 50 centimeters of water. Rightsided cardiac failure causes increased venous pressure in both legs and arms.

Dr Weiss delivered the last paper of the evening on "Malignant Hypertension of the Pulmonary Circuit." Dr Parker and he have studied the minute structure of the normal and pathological lung. Several excellent colored slides were shown. The normal alveolus has four layers in its wall: the capillary endothelium, two basement membranes, and the epithelial lining of the alveolus. In mitral stenosis the number of capillaries is not only increased but their diameter is three times normal and their walls are much thicker with an increase in the number of collagen fibres and a pericapillary edema. These abnormal vessels easily rupture which explains the pulmonary hemorrhage that occasionally occurs in these patients. The arterioles of the lung in mitral stenosis were frequently found to be almost obstructed by fibroblast-like cells. Dr Weiss spoke of this process which may have the character of a necrotizing arteriolitis due to hypertension of the pulmonary circuit and compared it with the arteriolar changes in the kidney in arterial hypertension of the systemic circuit.

MIDDLESEX EAST DISTRICT MEDICAL SOCIETY

At a meeting of the Middlesex East District Medical Society held January 8, at the Bear Hill Golf Club, Stoneham, Mass., Dr William E. Browne

of the Surgical Staff of the Carney Hospital spoke on treatment of infections and injuries of the hand and demonstrated the use of new splints used in such cases.

There were sixty members present.

OPPOSITION TO THE ANNUAL REGISTRATION OF PHYSICIANS IN MASSACHUSETTS

At this meeting it was unanimously voted that the Society go on record as opposing the bill for the Annual Registration of Physicians. Councillors of the Massachusetts Medical Society who were present were so instructed.

KENNETH L. MAOLAOHLAN, *Secretary*,
Middlesex East District Medical Society

MIDDLESEX SOUTH DISTRICT MEDICAL SOCIETY

Meeting on Wednesday, January 29, 1936, at the
Hotel Commander, Cambridge

Luncheon at noon

Short but important business meeting after the
luncheon

Speaker: Dr A. Warren Stearns, Dean of the Tufts
College Medical School

Topic: "The Role of the Situation in Nervous
Disease"

ALEXANDER A. LEVI, M.D., *Secretary*

HAMPDEN DISTRICT MEDICAL SOCIETY

The regular Winter Meeting of the Society will
be held in the rooms of the Springfield Academy
of Medicine, 20 Maple Street, Springfield, on Tues-
day, January 28, 1936, at 4 15 P.M.

PAPER FOR THE AFTERNOON

"Thrombosis in Veins as a Complication of Medical
and Surgical Diseases"—Dr John Homans of the
Peter Bent Brigham Hospital

Discussion by Fellows

Dinner at 6 P.M. at expense of the Society

HERVEY L. SMITH, *Secretary and Treasurer*
249 Union Street, Springfield.

CLINICAL CONGRESS OF THE AMERICAN COLLEGE OF SURGEONS

The 1936 annual Clinical Congress of the Amer-
ican College of Surgeons will be held in Philadel-
phia October 19-23

HARVARD MEDICAL SOCIETY

The next meeting of the Harvard Medical Society will be held in the Peter Bent Brigham Hospital Amphitheatre (Shattuck Street Entrance) Tuesday evening, January 28 at 8 15 P.M.

PROGRAM

Presentation of Cases.
Reactions to Ovarian Hormones. By Edgar Allen M.D., Yale University
Medical students and physicians are cordially invited to attend.

MARSHALL N. FULTON M.D. Secretary

NEW ENGLAND HEART ASSOCIATION

The next meeting of the New England Heart Association will be held at the Beth Israel Hospital Boston - Mass. Moody February 3 1936 at 8 15 P.M.

PROGRAM

1. A Case of Coronary Occlusion with Interesting Features Dr Harry B. Levine.
2. Evaluation of Medicinal Treatment of Angina Pectoris. Dr Joseph E. F. Ruseman
Studies on the Effect of Nitroglycerin on Angina Pectoris. Dr Morton G. Brown.
3. Incidence of Coronary Heart Disease and Hypertensive Heart Disease in Different Population Groups Dr Louis Silver
4. The Cardiac Output in Patients with Congestive Failure after Total Thyroidectomy Dr Mark D. Altshuler.
5. A Clinical and Pathologic Study of Aortic Stenosis Dr Louis Wolf and Dr Monroe Schlesinger
6. A Summary of Clinical Experience in the Treatment of Chronic Heart Disease by Total Thyroidectomy Dr Herrman L. Blumgart.

All members of the New England Heart Association and interested physicians are invited to attend.

JAMES M. FAULKNER, M.D., Secretary

SOCIETY MEETINGS
CONGRESSES AND CONFERENCESCALENDAR OF BOSTON DISTRICT FOR THE WEEK
BEGINNING MONDAY JANUARY 27 1935

Tuesday January 28—

- *9 10 A.M. Boston Dispensary, 25 Bennet Street, Boston. X-Ray Demonstration Dr Alice Ettinger
- 2 30 P.M. Pediatric Ward Visit, Massachusetts Eye and Ear Infirmary
- 8 15 P.M. Harvard Medical Society Peter Bent Brigham Hospital Amphitheatre (Shattuck Street Entrance)

Wednesday January 29—

- *9 10 A.M. Boston Dispensary, 25 Bennet Street, Boston. Pediatric Case Presentation. Dr Francis McDonald.
- 11 2 A.M. Clinico-Pathological Conference. Children's Hospital.
- 5 P.M. Arthritis Clinic. Robert Breck Brigham Hospital.
- 8 15 P.M. Suffolk District Medical Society Joint meeting with the Boston Medical Library at the Boston Medical Library

Thursday January 30—

- *8 30-9 20 A.M. Clinic, Surgical and Orthopedic Staffs of Children's Hospital, at the Children's Hospital.
- *9 10 A.M. Boston Dispensary, 25 Bennet Street, Boston. Case Histories in Brain Tumors. Dr J. J. Skirball.
- 3 30 P.M. Medical Clinic at the Peter Bent Brigham Hospital.

Friday January 31—

- 9 10 A.M. Boston Dispensary, 25 Bennet Street, Boston. The Heart and Aorta in Chronic Hypertension. Dr Paul Dudley White
- 13 M. Massachusetts General Hospital, Clinical Meeting of the Staff of the Children's Medical Service. Ether Dome.

Saturday February 1—

- 10 12. Staff rounds at the Peter Bent Brigham Hospital.

Sunday February 2—

- 4 P.M. Free Public Lecture, Harvard Medical School Building D Longwood Avenue. The Prevention and Treatment of Physical Diseases of the Month. Dr L. M. S. Miner

BOOK REVIEWS

A Textbook of Bacteriology Thurman B. Rice 551 pp Philadelphia and London W. B. Saunders Company \$5.00

This short textbook of bacteriology covers the field in a fairly adequate manner for elementary students of the field. It is, however, insufficient in its considerations of the subject to satisfy the medical student or physician who turns to it for information. Thus, the Brucella group is dismissed in five pages and the paratyphoid in less than three. The first ten chapters are devoted to a brief introduction of bacteriology and methods of staining, cultivation and disinfection.

Traitement des Fractures et Luxations des Membres Jacques Leveuf, Charles Girode et Raoul Charles Monod 447 pp Paris Masson et Cie 50 fr

This textbook by the pupils of Professor Pierre Delbet is the outgrowth of thirteen years' experience in teaching the treatment of fractures and dislocations to medical students at the Hôpital Bretonneau. It is written in a clear and simple manner, with excellent illustrations of the various therapeutic procedures. There is no bibliography and practically no discussion. The methods used differ very little, with few exceptions, from those in common use in the United States. The most striking departure, on the whole commendable, is the widespread advocacy of constant traction in most ingenious fashion, for the reduction of both fractures and dislocations. The book, designed chiefly for medical students, is written in a somewhat dogmatic manner. It should prove to be a most useful textbook, as well as a helpful book of reference for practitioners.

NEW ENGLAND SURGICAL SOCIETY

CONGENITAL ABSENCE OF THE PERICARDIUM*

With Report of a Case

BY WILLIAM E. LADD, M.D.†

ABSENCE or deficiency of the pericardium is one of the rarer of the congenital malformations. The condition was first accurately described by Baulhe¹ in 1788 though it had been mentioned by Realdus Columbus as early as 1559. Since that time reports of individual cases have been made in the literature occasionally. By 1925 Moore² was able to collect sixty-four cases and by 1931 Beck³ was able to collect sixty-seven cases including one reported by himself. In this series there are several in which other congenital anomalies were found but only three which were associated with diaphragmatic hernia. These three cases were reported by Rissel (see Moore). Two of the cases were found in the fetus and the third in an infant who died immediately after birth.

In one fetus the hernia was a true diaphragmatic hernia on the left side with displacement of the thoracic and abdominal organs. In the other fetus and infant dying at birth the hernia was a false one with displacement of the abdominal and thoracic organs. In all these three instances there were numerous other associated anomalies quite incompatible with life. It is surprising that these two malformations have not been found together more commonly when one considers the very intimate developmental connection between the pericardial, pleural and peritoneal cavities. All the cases of pericardial deficiency in the literature have been autopsy reports. The condition is apparently not incompatible with an active life, nor does it have an effect on longevity. In no instance was it considered to be responsible for the death of the patient. The case here to be reported is, so far as I know, the only case in which the condition has been recognized during life. In this instance it was not diagnosed but was a chance finding in the course of an operation for the repair of a diaphragmatic hernia.

The patient, a female child two years of age, was referred by Dr. Walter L. Sargent of Quincy for the treatment of diaphragmatic hernia.

P.H. The mother is twenty-nine years old, the father thirty-three years old and both are living and well. There are four other children all living and well. There were two pregnancies antedating the living children which terminated at six months. One premature baby lived one hour only and the other twelve hours. There is no family history of lines and there is no other relevant factor in the family history.

P.H. The patient was born at full term and by a normal delivery. The birth weight was 7 lbs., 14 oz. When feeding was attempted the baby became cyanotic, choked and regurgitated. This difficulty appeared to be more marked with breast than artificial feeding. She was therefore removed from the breast and fed on a lactogen formula. At this time diaphragmatic hernia was suspected and confirmed by x-ray studies. For several weeks the baby continued to have cyanotic attacks when fed and remained on the danger list at the Quincy Hospital. At the end of three months sufficient improvement had taken place for the patient to be discharged from that hospital. From that time until she was two years old and entered the Children's Hospital she had weathered an attack of measles, German measles and chickenpox but had failed to gain weight satisfactorily. At two years of age she weighed 13 lbs. which is slightly under the normal weight for an infant of one year.

P.E. Examination showed an undernourished small girl of good color. Chest. Percussion over the left chest posteriorly revealed dullness below the 3rd rib and from the midline to the posterior axillary line. Anteriorly the percussion note was tympanitic. Breath sounds on the left were distant and only vaguely heard. Percussion of the right chest was hyperresonant but the breath sounds were normal and no rales were heard. Heart. The borders of the heart were difficult to define by percussion. The apex impulse could not be felt. The heart sounds were distant without murmurs of normal rhythm and rate of 100. Abdomen. This was flat or perhaps a little scaphoid in appearance. The liver edge was 1½ cm. below the costal border in the nipple line. The spleen was not palpable. No tenderness, muscular spasm or palpable masses were felt.

Laboratory Data

Urine normal
Blood 70 per cent Hgb. 4,150,000 R.B.C. 8700
W.B.C. Normal smear. Type IV. Mother type IV compatible. Tuberculin test negative.

X-Ray. Fluoroscopic examination showed the esophagus displaced slightly to the right. The

†Ladd, William E.—Chief of Surgical Service, Children's Hospital, Boston. For record and address of author see "This Week's Issue," page 217.

barium entered the stomach without difficulty. The whole of the stomach was in the thoracic cavity, inverted, and with the greater curvature against the chest wall lying superiorly while the pylorus was lying inferiorly. At six hours after the administration of the barium it was all in the colon. The cecum and ascending colon were in the left side of the chest with the appendix visualized just lateral to the heart. There was apparently a portion of the left side of the diaphragm present anteriorly and a portion posteriorly.

Interpretation. Left sided diaphragmatic hernia.

FIG 1 Preoperative anteroposterior x-ray of stomach in thorax.

Preliminary Operation

Under avertin and novocain anesthesia a small transverse incision was made in the left side of the neck an inch above the clavicle. The outer border of the sternomastoid was retracted toward the midline and the phrenic nerve exposed on the scalenus anticus muscle. The nerve was crushed with a small hemostat and the wound closed with interrupted silk sutures to the fascia, platysma muscle and a subcuticular silkworm gut suture to the skin.

Second Operation

Four days after the preliminary operation the abdomen was opened under avertin ether anesthesia. A left rectus incision was made extending from the costal border to a point about an inch below the umbilicus. The peritoneum was incised and the peritoneal cavity and diaphragm inspected. There was an opening about three inches by two in the left side of the diaphragm extending from the nipple line toward but not connecting with the esophageal opening. Above the opening in the diaphragm in the thoracic

cavity was found the whole of the stomach, the spleen, the splenic flexure, half the transverse colon and about four or five inches of the descending colon. These organs were very easily delivered from the thoracic cavity there being only a few light adhesions around the cardiac end of the stomach. The abdominal viscera presented the not very uncommon condition of an unrotated colon with a rudimentary mesenteric attachment. There was no oblique attachment to the posterior abdominal wall of the mesentery of the small bowel and only a small area of attachment of the hepatic flexure of the colon. The cecum and ascending colon were lying loose in the epigastrium just under the hernial opening. An incision was made around the edge of the hernial opening through both the peritoneal and pleural layers. As soon as the pleura was opened and air entered the thoracic cavity the sac was delivered with no difficulty and completely excised. On looking through the opening in the diaphragm the lung was seen collapsed and the heart next to it.

FIG 2 Preoperative lateral x-ray of stomach in thorax

in the same cavity without any pericardial covering. The ventricles stood out plainly to their base. I could not see the auricles and do not feel sure there was not a rudimentary pericardium as found in some of the autopsy reports. The hernial opening in the diaphragm was closed with one row of interrupted sutures of silk to the pleural layer, one row of mattress sutures of silk to the musculature of the diaphragm, and another row of interrupted silk sutures to the peritoneal layer of the sac. The abdomen was closed in layers without drainage.

Pathologic Report

GROSS DESCRIPTION The specimen consists of a thin-walled sac measuring approximately 10 cm. in diameter. The wall of this sac is composed of two layers of thin membranes which are entirely asprated from each other except along one side for a distance of approximately 4 cm. In this region the membranes are fused and between them is a thin layer of muscle fibres. Both surfaces of each membrane are clear grayish in color smooth moist, glistening free from exudate and inflammation. Several petechial hemorrhagea are noted in both

mation of a cavity in the manner in which the pericardial and other serous cavities are formed in the embryo. There are no definite masses of cells however. In addition, bundles of smooth muscle are found from place to place.

DIAGNOSIS Diaphragmatic hernial sac.

SUNNY FARRER, M.D., Pathologist

Convalescence

The first twenty four hours after operation were somewhat stormy. The temperature rose to 104 F., the pulse to 160 and the respirations to 60 to the minute. The systolic blood pressure was 70 and the diastolic 20. At the end of another 24 hours the temperature had dropped to 101, the pulse to 130 and the respirations to 25. The blood pressure was 90/58. During this period there was an almost complete left sided pneumothorax with an almost complete collapse of the left lung. A 90 per cent collapse of the left lung was estimated by the roentgenologist at this time but without displacement of the heart. From this time on the convalescence progressed satisfactorily and uninterruptedly. The patient was kept in the hospital a longer

FIG. 3. Preoperative lateral x ray of colon in thorax.

FIG. 4. X ray four months postoperative.

layers. Sections are fixed in Zenker's. The rest of the specimen is preserved in formalin.

MICROSCOPIC Six sections. Both surfaces of the sections are covered by very dense connective tissue. There is no inflammatory reaction. The mesothelial cells are seldom seen and in the few areas in which they are preserved marked fragmentation is seen. The central portions of the tissue are composed in part of bands of collagen fibers which run roughly parallel to one another and are very closely packed together. Striated muscle is almost entirely lacking. Among the collagen fibers are numerous duct-like structures. These are lined by cuboidal epithelium. They present lumina of various sizes but the lumina are mostly small. All of them are empty. They are not surrounded by a definite connective tissue wall and there is no inflammatory cellular infiltration in that region. The interpretation of the histogenesis of these structures is difficult. Dr. Wolbach suggested that they might be small portions of mesenchymal tissue with early for

time than usual to make sure that there were no circulatory disturbances and until the lung was entirely expanded. She was discharged on the 28th day after operation. The wound was healed per primam with a firm scar. The abdominal organs were in the abdominal cavity. The lung was completely expanded and there was no air or fluid in the pleural cavity. The x-ray report at this time stated that the heart was slightly displaced to the left, but there was no other abnormality. The child's general condition was excellent. Follow-up examination was made September 23, 1935, four months after the operation. The child has gained four pounds in weight, has had a good appetite and the bowels have moved normally. The systolic blood pres-

sure was 86 and the diastolic 50. The x-ray examination showed the left diaphragm in the normal position and moving with respiration. It also showed the stomach and abdominal viscera in their normal position.

It is interesting to speculate as to whether the somewhat stormy convalescence of this child for the first forty-eight hours after operation had any relation to the absence of the pericardium. There are no clinical data on this particular situation and for the nearest analogous conditions one must turn to experimental work and to human beings who for one reason or another have had the pericardium opened.

Beck and Cox⁴ did some experimental work to determine what effects on the mechanics of the circulation were produced by exposure of the heart to atmospheric pressure. They concluded from their experiments that when the heart was exposed to atmospheric pressure the minute output of the heart fell about twenty per cent. They considered the changes produced as a pressure phenomenon and applied the term of pneumocardiac tamponade for this mechanism. They suggest that atmospheric pressure on the heart might be a factor in producing cardiac failure.

Blalock⁵, on the other hand, exposing the heart to atmospheric pressure in experiments performed with a slightly different technic, concluded that, "No definite alterations in the arterial pressures were noted and the changes in the output of the heart were not marked."

Amerio⁶ concluded from experimental work on rabbits that total resection of the pericardium did not affect the life of the animal. These conclusions of course tally with certain clinical data and with the histories of patients with the condition that is the subject of this paper and, for what it is worth, with the progress of this reported case so far. The patients who have had the pericardium opened for pericarditis or other reasons do not, so far as I know, suffer from the heart being exposed to atmospheric pressure.

COMMENT

A case of congenital deficiency of the pericardium is here reported increasing the number to be found in the literature to sixty-eight. It is believed that this is the only case of this condition to be recognized during life. From the literature one may conclude that the condition is compatible with an active life of normal duration.

The question of the effect of atmospheric pressure on the heart is debatable and depending on this, one should consider the desirability of taking steps to reduce the pneumothorax which follows this type of operation. In this instance the air was allowed to absorb gradually and the outcome was fortunate.

DISCUSSION

DR. THOMAS H. LANMAN, Boston, Mass. This case of multiple anomalies just presented brings up the question of how often these developmental defects are multiple. I think the teaching, as I remember it, was that they very frequently are. However, in a series of 592 cases of congenital anomalies only eighty-two, or 13 per cent, showed more than one anomaly. But in these 592 cases there is a series of 167 that had anomalies of gastrointestinal tract and in this 167, seventy, or 41 per cent, showed more than one anomaly.

I think it is fair to say then that in discussing multiple anomalies, they are very likely to be present in cases that involve the development of the gastrointestinal tract, as was the case here.

In the treatment of a case of this sort, there are three things that we have found of value. In the first place, the preliminary crushing of the phrenic nerve has seemed to us to be of very distinct value in diaphragmatic hernia and lobectomy. It is easily done. Even in infants it can be done under avertin and novocain.

The abdominal approach for the repair of diaphragmatic hernia, we believe, is best in these children where it is very likely to be a true hernia with a true sac. In the first place, it seems advisable whenever possible to do as little as we can in having a wide open wound of the thorax. If you are unable to reduce the hernia you can always make an additional incision exposing the thoracic cavity.

As regards the reexpansion of the lung, and that brings in the question of anesthesia, we feel quite confident that in a case of this sort and in the few cases where we have done lobectomies, that the complicated intratracheal anesthesia is not needed to give us reexpansion or control over the expansion of the lobe of the lung. As was true in this case, the lung came out very readily. While we do have suction apparatus to get rid of the secretion which, of course, is important in some of these cases, we do not feel that it is necessary to complicate the anesthesia with its added danger of using the intratracheal tube.

I think in this case, the absence of the pericardium probably did not have anything to do with the somewhat stormy convalescence this youngster showed the first twenty-four or forty-eight hours. Certainly, after any lobectomy or operation that involves manipulation around the thorax, they are very apt to have a stormy time.

Also, against opening wide the thorax, is the fact that we like to minimize in so far as we can, the accumulation of serum in the chest cavity, and it seems to us the abdominal approach does minimize that better than a wide thoracic approach.

PRESIDENT JOHNSON Dr. Parker:

DR. DAVID W. PARKER, Manchester, N. H. I appreciate the courtesy of being asked to discuss this paper. I must confess, however, that I have had no personal experience with the condition.

Upon consulting the literature, I found three articles, one by Richard L. Moore of Boston, in the Archives of Surgery November 1925 one by James C. Wint, Professor of Anatomy at the University of Toronto in the Archives of Surgery December 1931 and another by C. S. Beck, Archives of Surgery February, 1931. All of these articles were highly technical and dealt to a great extent with the embryology of this anomaly. Wint, in his article, however did state that in three hundred and seventy-one years, only sixty-six cases had been reported in the literature. He also stated that the diagnosis of this condition had never been made during life but always from autopsy and that in none of the cases reported had it been a factor in the cause of death. It occurred not infrequently in men who had done hard work all their lives. I was unable to find in any of the articles which I reviewed that this anomaly was inconsistent with an active life or a factor in dilation or enlargement of the heart. I think, therefore, it is fair to assume that the absence of the pericardium is of more interest as a rare anatomical curiosity than as a clinical entity.

It is very interesting that Dr. Ladd should oc-

cupy the unique position of being the only man who has ever made a diagnosis of this condition during life.

Dr. JAMES W. SEVER, Boston, Mass. I should like to ask Dr. Ladd one question, if I may.

What was the cause of the original diagnosis at Quincy Hospital? What led to the diagnosis originally in the baby you saw a few weeks old? What were the indications at that time?

Dr. LADD She had the typical symptoms which almost all these babies with diaphragmatic hernia have, cyanosis, difficulty of feeding and regurgitation. Of course, with the congenital hernia in the left side which is very much the most common place some of them have true hernial sacs, some are false hernias but the result is much the same. The operation for true hernia is rather easier to perform.

The other conditions of course, which might be confused with this are the esophageal atresia, tracheal esophageal fistulas and the other forms of esophageal obstruction.

THE QUESTION OF "INFLUENZA" AND ATYPICAL PNEUMONIA*

BY JOHN W. CASS, JR., M.D.†

INTRODUCTION

THERE have been mild "influenza" epidemics throughout Greater Boston during the winter and spring of the past two years. Accompanying these epidemics, there have been an unusual number of atypical pneumonias.

It has been my privilege to see a number of these atypical infections in private practice, on the wards of the Massachusetts General Hospital and among the nursing staff at the New England Deaconess Hospital. It was very striking to notice the degree of confusion regarding the diagnosis, treatment, and prognosis of these infections. A total of seventy-two cases furnished the material for this discussion. A division into three groups is made to simplify the presentation of the material.

The first group consists of fifty-three cases, each of which it was felt justifiable to call "influenza." In doing this the criteria laid down by Thomas Francis¹ were used, namely, "sudden onset with constitutional symptoms, chilliness, fever, myalgia, headache, mild respiratory symptoms without coryza, the presence of leucopenia, and a course of two or three days which was followed by considerable asthenia and exhaustion." These patients all recovered and the only points of interest were that six developed mild pansinusitis with symptoms of this complication of from four to seven days' duration. These cases all responded to medical

treatment. Two other patients developed acute otitis media both unilateral, and both requiring paracentesis.

The second group consisted of seventeen cases in which, in addition to the clinical picture of influenza, definite signs of chest involvement were present and the active course of the disease extended over a period of five to sixteen days.

The third group consisted of two cases, both fatal, which developed hemolytic streptococcus empyema.

CLINICAL PICTURE

The physical examinations of the patients in the first group revealed marked prostration, and injection of the conjunctiva and nasopharynx. Similar findings were present in the Group II cases, plus dullness and impaired breath sounds, this being usually at one base, commonly the left, and rarely bilateral. These findings were the usual ones when the patient was first seen. A customary course in the Group II cases was that fine, moist, crepitant rales were next heard over the involved area and these persisted even after the dullness and impaired breathing cleared. Frank bronchial breathing was picked up rarely.

In Group III, the findings were essentially the same with a rapid extension of the physical signs in the chest, the process in one case rapidly extending to the other lung.

In addition to the symptoms considered necessary for diagnosis, all patients complained early of vague abdominal distress with marked distention and anorexia. The outstanding com-

*I wish to acknowledge the general help and advice of Dr. Donald S. King and Dr. Dwight L. Miesco, also the bacteriological aid of Dr. Morris Leader of the Massachusetts State Department of Health.

†Cass, John W., Jr.—Assistant in Medicine, Massachusetts General Hospital. For record and address of author see "This Week's Issue" page 217.

plaint in addition to prostration was cough, this being harsh, dry, nonproductive, and coming in paroxysms. Paroxysms were particularly frequent during the latter part of the afternoon and during the night. They were also brought on at any time by movement or physical effort on the part of the patient, or marked change in temperature of the room.

The patients with chest involvement were subject to waves of cyanosis which were particularly alarming, in addition to the constant appearance of extreme toxicity.

The two patients with empyema complained of severe pleural type of pain. The temperature was of the septic type and varied only in degree and duration in the different groups. The temperature returned to normal in all cases by lysis. The pulse, characteristically, was not so high as one would expect in all except the fatal cases.

BACTERIOLOGY

The bacteriology was inconsistent and very little was done in the first group, eleven cases having throat cultures, all of which showed the usual mouth organisms plus a predominance of hemolytic streptococci. Good sputum specimens were not obtainable. Sputum of a sort was obtained in seven cases of Group II, and in only three of these seven were pneumococci found of sufficient viability to kill a mouse, two being subgroups of the usual Group IV, namely Groups XXII and XIII. The third was a definite Type II pneumococcus. Sputum of all seven cases on culture yielded predominantly hemolytic streptococci. Blood cultures in all cases of Groups II and III were negative. Likewise, agglutination tests for typhoid and undulant fever were negative. Hemolytic streptococci were found in the urine of five cases from the second group. Hemolytic streptococci were found in the chest fluid of both fatal cases.

BLOOD PICTURE

The blood picture in the first group of cases showed a mild leucopenia of four to six thousand with a polymorphonuclear count of 75-80 per cent. Leucopenia was usually more marked in the second group, being characteristically between 2500 and 4500 white blood cells with a polymorphonuclear count of 80-90 per cent. In this group, the sickest patients had the lowest white blood counts, the most marked being that of 1800 white blood cells. Both fatal cases rapidly developed an extreme leucocytosis of 70,000 to 90,000 white blood cells with a polymorphonuclear count of 93-96 per cent.

X-RAY EXAMINATION

Chest films were taken in twenty of the first group, and all were negative. Fourteen of the second group were x-rayed and all showed areas of increased density conforming to the physical

signs. One of the fatal cases was x-rayed and the findings were interpreted as diffuse consolidation with no evidence of fluid. Streptococcus pus, however, was obtained on paracentesis.

In regard to the point of contagion, it was interesting to find that in Group II, four of the cases were in one family, two in another, and two more in still another family, while most of the Group I cases were among the nurses at the Deaconess Hospital, but three of these having pulmonary involvement.

COMPLICATIONS

Very few complications were met with among the simple cases, those found being mild sinusitis and otitis media as previously stated. Rather severe pyorrhea occurred in five cases of the second group with some degree of loss of hair in all, none going on to total alopecia. One patient in the second group at the time of discharge still had evidence of atelectasis. Another patient in this group developed Type II pneumonia. Of the fatal cases the patients died with a hemolytic streptococcus empyema, one proved by autopsy, the other by chest paracentesis prior to death.

An interesting case seen and not included in the report because it was not seen during the phase of respiratory infection gave a history of typical influenza and then after five days developed symptoms of peritonitis. At operation, a localized pocket of pus was found under the liver. No cause could be demonstrated for this infection and a pure culture of hemolytic streptococci was obtained from the material. The patient died, but a postmortem examination was not obtained.

It is interesting to note that two cases of Group II had a similar pulmonary infection six to ten months following their initial pneumonia.

TREATMENT

Symptomatic therapy was the only available routine. There was a definite tendency of all patients not to perspire unless given aspirin and they were very uncomfortable with a temperature of 102-104 degrees unless perspiration was induced. Aspirin, grains ten, with codeine, grains one quarter or one half, given three to five times during the twenty-four hours, gave very satisfactory results. Morphia, grain one-eighth or one-quarter, by hypodermic injection, was occasionally used. Nucleotide was given on the advice of a consultant in one case in the second group and a severe reaction followed this therapy. The cough was particularly troublesome and difficult to control. Oralsodium or phenobarbital taken throughout the day seemed to help by promoting general relaxation of the patient. Expectorants and benzoin inhalants appeared to aggravate the

cough. The fatal cases were too fulminating to allow any thought of surgical intervention and received simply symptomatic treatment.

PROGNOSIS

The question of prognosis is an extremely difficult one. All the cases were identical at onset, and there appeared no way of determining which would terminate in a few days which would develop chest involvement, or which the fatal complication of empyema. A good prognosis appears to be present in which the picture is typically that of straight influenza with no chest involvement. If there is evidence of chest infection, the prognosis is probably good no matter how sick the patient appears if the leucopenia persists and if the remainder of the clinical picture is satisfactory. The fatal cases developed chest pain, rapidly increasing leucocytosis, and signs of a rapidly advancing process in the chest.

DISCUSSION

There appears to be a specific infection which we now call "influenza." The etiology of this clinical picture is still in doubt. The weight of evidence in the literature in the past has been in favor of the influenza bacillus. However, Francis¹, working in the Rockefeller Institute, and Topley², in the London School of Tropical Medicine and Hygiene, have claimed the etiological agent to be a filtrable virus. There is also the possibility that a specific hemolytic streptococcus may be the etiologic agent.

The literature on this disease is extremely confusing, the great bulk of it dealing with epidemics. A clear-cut clinical picture is commonly present only during the early period of the various waves constituting an epidemic. During the height of the waves, the variety of complications is so great that the data collected may be misleading.

The typical case is so similar to what is commonly called "grippe" that the diagnosis is probably not made unless there is a recognized epidemic present. The complications of the typical cases are usually infections of the sinuses and ears. These seldom require surgical treatment other than paracentesis of the ear. Rarely, there may be a true pneumococcus pneumonia as a complication. The cases of pulmonary involvement included in this material were strikingly similar. Many other pneumonias were seen with white blood counts of 6 to 20 thousand and which were not proved pneumococcus pneumonias but whose clinical pictures were so different one from the other that no consistent material could be obtained from them.

With the present available data it is impossible to state that the cases classified as Group II were not simply complications of in-

fluenza. However, their clinical pictures were so strikingly similar and hemolytic streptococci were so commonly found associated with the disease that it is difficult for me to classify them other than as a specific type of pneumonia. They were not seen during the height of a severe influenza epidemic and their similarity thus conforms to the proper time element. The two fatal cases definitely terminated with a hemolytic streptococcus empyema or pleurisy, and undoubtedly also a septicemia.

It appears important to be familiar with the specific picture of what is called simple influenza and cases showing chest involvement with similar clinical pictures, as well as being cognizant of the possibility of the manifold clinical pictures that can occur once a real epidemic is present and during which a clear resemblance to a specific infection is lost. Prognosis, at the best, is extremely difficult but a more rational attempt can be made if one is familiar with the specific simple case as well as the specific cases with chest involvement. The disease is unusually treacherous because of the complete submission of the resistance of the patient and there appears to be no way in which to predict the ultimate clinical course.

All patients should be promptly put to bed and the convalescence prolonged well after the termination of clinical activity, no matter how mild the clinical course has been. It is now felt by many that bronchiectasis is definitely a late complication to fear in influenza, particularly in those patients having evidence of infection in the lungs during the active course of the disease.

The following material is presented to illustrate some of the most interesting clinical points.

CASE L. M. The chart is presented to demonstrate a typical temperature and white blood count curve in the cases showing pulmonary involvement. These curves vary only in duration from the curve found in the simple cases. As the temperature curve falls the white blood count tends to rise and a mild leucocytosis finally occurs. The chart presented is that of a case representing one of a group of four identical infections in a single family.

CASE D. P. The chart is that of a fatal case. The onset in no way varied from that in any other patient. On the sixth day of the disease there was severe pleural pain followed by leucocytosis which rapidly increased to 87,000 shortly before her death. A complete postmortem report follows.

Fifteen and one-half hours postmortem.

Anatomic Diagnoses

Pleuritis, acute purulent bilateral with multiple empyema cavities on the left.

Bronchopneumonia.

Pulmonary collapse left upper and lower lobes.

Pericarditis slight

Subdiaphragmatic abscess small left

Salpingo-oophoritis, subacute, left

Cystitis

Cholelithiasis.

Cholesterosis

Heart not examined

The body is that of a slightly obese woman of forty-two years, measuring 167 cm in length and weighing approximately 160 pounds. There are puncture wounds in both antecubital fossae. The abdomen is protuberant and tympanitic. There is a plentiful amount of subcutaneous fat and the muscles are well developed.

Peritoneal Cavity On opening the peritoneal cavity the large bowel is found to be redundant and marked-

floating particles of yellowish exudate. The pleural surfaces are irregularly covered with loosely adherent yellowish fibrinopurulent exudate and small collections of thick yellowish pus are held in the interpleural spaces. Left pleural cavity. See left lung. The pleural surfaces of both diaphragms show a marked dilatation of the vessels.

Thyroid Not removed.

CASE L M.

iv distended with gas. There is no fluid and the peritoneal surfaces are glistening.

Trachea and Bronchi Slightly injected and are filled with frothy whitish fluid.

Bronchial Glands Soft and moderately enlarged.

Lungs Right Lung. The right lung is crepitant throughout. The surfaces are covered with fibrinopurulent exudate. On section the upper and middle lobes are reddish pink with small, ill defined, slightly raised, indurated areas of the same color. Considerable fluid exudes on pressure. The lower lobe on section is dark red and no induration can be made out. Considerable bloody fluid exudes on pressure.

Left Lung. On removal of the chest plate the left lung appears to be partially collapsed. There are approximately 800 cc of turbid yellowish fluid on which a considerable amount of free yellowish exudate floats. The anterior border of the upper lobe is completely collapsed and held between two partially walled off empyema cavities. The larger involving the superior lateral aspect measures approximately 15 x 7 x 6 cm and is full of thick yellowish pus. The smaller is poorly walled off and involves the superior mediastinal pleural surfaces. On freeing the lung from loosely adherent points, a considerable amount of pus escapes from the interpleural space laterally. On section, the posterior and lower portions of the upper lobe are found to be grayish pink and contain several small slightly raised areas, the largest approximately 1 cm in diameter. The lung in the collapsed upper anterior portion of the upper lobe is a dirty gray color. Section of the lower lobe finds it to be for the most part collapsed with no areas of induration.

CASE D P

Appendix, Esophagus Negative.

Stomach Moderately distended and contains a dirty grayish brown lumpy fluid.

Intestines Negative.

Mesenteric and Retroperitoneal Glands Negative.

Margin of Liver Well above the costal margin.

Diaphragm Fourth space on both sides.

Pleural Cavities The right pleural cavity contains approximately 500 cc of cloudy yellowish fluid with

Pericardium Contains approximately 200 cc of straw colored fluid with a small amount of stringy yellowish exudate. The parietal pericardium opposite the empyema cavity above described is considerably thickened and there is very slight roughening and injection on the cardinal surfaces.

Heart Weighs 300 Gm. The left ventricle contains a considerable amount of clotted and hemolyzed blood. The right ventricular wall measures 4 mm. the left 12. The mitral valve measures 11 cm., aortic 7 tricuspid 13.5 pulmonary 8.5. They are all negative. There is no evidence of endocarditis.

Coronaries Negative.

Aorta Measures Ascending 7.5 cm., arch 5.5 descending 5. There is very slight atheromatous change.

Pulmonary Artery Venae Cavae Negative

Liver Weighs 2100 Gm. The surface is smooth reddish brown and on section is not remarkable.

Gallbladder Contracted. There is considerable subserosal fat. It contains three rounded papillary greenish stones, the largest measuring 1 cm. in diameter. The mucosa is studded with flecks of yellowish material.

Bile Ducts Negative

Pancreas Ducts Negative

Spleen Weighs 200 Gm. On its superior pole there is a small collection of yellowish fibrinopurulent exudate which corresponds to a small area on the diaphragm measuring approximately 1 cm. in diameter which also shows adherent exudate.

Adrenals Not remarkable

Kidneys Weigh 350 Gm. The capsules strip with ease, leaving a smooth reddish brown surface. On section the cortex measures 7 mm. The markings are distinct. The pelves are negative.

Ureters Bladder Negative

Uterus Tubes and Ovaries Small. The right tube and ovary are negative. The left tube appears to be slightly swollen. Its fimbriated end is closed. The left ovary is soft and a cyst approximately 2.5 cm. in diameter which contains thin pusy material is apparently attached to it. The ovary and tube are bound down to the peritoneal surfaces of the pelvis and there is some fibrinopurulent exudate in this area.

Gross Diagnoses

Diffuse purulent pleuritis bilateral with multiple empyema cavities on the left.

Bronchopneumonia right upper and middle lobes left upper lobe

Pulmonary collapse left upper and lower lobes

Pericarditis slight

Subdiaphragmatic abscess, small left.

Salpingo-oophoritis, acute left.

Cystitis.

Cholelithiasis

Cholesterosis

Note There is a peculiar sweet penetrating odor about the body which is most marked in the vomitus but is particularly strong when the pleural cavities are opened.

Bacteriological Examination Heart's blood and pleura Hemolytic streptococcus

Microscopic Examination

Heart Negative

Lung One section shows a cellular exudate on the pleura with congestion of the underlying lung. There

is edema of the lung but no evidence of pneumonitis. Another section shows pneumonitis of the underlying lung tissue with marked cellular exudate. This section shows marked atelectasis.

Liver There is hyalinization of the arterioles and an increase in polymorphonuclears.

Adrenal Negative

Kidney There is an occasional hyalinized glomerulus congestion and cloudy swelling of the tubular epithelium.

Tube and Ovary Show a subacute inflammatory process with numerous eosinophiles.

Diaphragm Shows a cellular exudate on both sides and a small amount of lung tissue, the alveoli being filled with polymorphonuclears.

Bone Marrow Appears to be hyperplastic.

Case M. H. The accompanying x ray is presented as the usual radiographic findings in a case with pulmonary involvement. There is nothing specific

CASE M. H.

In the type of x ray findings. The area of dullness suggests a lobar distribution. The process cleared in fifteen days without the patient raising any sputum.

Case E. R. These x rays are those of a case with pulmonary involvement. The x ray findings are of interest and were first diagnosed as being due to tuberculosis. The clinical picture was in no way different from any other case in this group. The first x ray was taken on admission showing a lesion in the left infrascapular area. The second x ray was taken two days later showing a spread to the middle portion of the other lung and the third plate was taken at the time of discharge, after a stay in the hospital of twenty days. This patient was seen six months after her discharge from the hospital. She was well and her chest was entirely clear both by physical examination and by x ray.

CASE E R. (1)

CASE E R. (3)

CASE E R. (2)

CASE M K. (1)

CASE M K The accompanying x-rays are those of a fatal case. The first plate was taken on admission the second plate twenty four hours later and

CASE M K (-)

but a few hours before death. They demonstrate how rapidly the process can spread in a short time. The patient had been followed at home for four days and shortly after admission complained of severe pleural pain in the left chest with signs of a rapidly progressive lesion. A chest tap a few hours before death yielded thin pus from which a pure culture of hemolytic streptococci was obtained. Permission for a postmortem examination could not be secured.

CASE J M These x-rays are those of a case with pulmonary involvement. The first plate taken on admission shows an extensive process on the right with a shift of the mediastinum to this side. The second plate was taken six weeks later at the time of discharge. They demonstrate that this type of infection can be a destructive process leaving after it considerable damage. Repeated chest taps failed to find fluid and at discharge the patient was symptom free. He was seen at home by a house social worker three months after discharge and the patient stated that he was in good health other than for chronic rheumatism which he had had for many years. However it is still possible that he may have trouble from the area of atelectasis and scarring which has followed this infection.

SUMMARY

Seventy two cases of "influenza" are presented, fifty three or 73.6 per cent being typical "influenza", seventeen or 23.6 per cent in "influenza" with pulmonary involvement two or 2.8 per cent "influenza" with pulmonary involvement complicated by empyema and a fatal outcome. Of the nineteen cases with pulmonary involvement two or 10.5 per cent developed fatal hemolytic streptococcus empyema.

A PARTIALLY PURIFIED LIVER EXTRACT
THERAPEUTICALLY EFFECTIVE IN PERNICIOUS ANEMIA*

BY Y SUBBAROW, PH D,† BERNARD M JACOBSON, M D,† AND CYRUS H FISKE, M D †

IN the course of experiments on the isolation of the hematopoietically active liver material it was found, in April, 1933, that filtrates of charcoal adsorption on therapeutically active liver extracts were inert in pernicious anemia. Attempts to extract the active material from the charcoal with a variety of eluents were begun in June, 1933. None of the eluents studied, among them isopropyl, butyl, and amyl alcohols, yielded products from different batches of crude liver extract that were consistently therapeutically active. Since September, 1934, elution by means of ethyl alcohol has always resulted in active extracts. Mention of this procedure has already been made in a previous communication¹. The preparation and biological activity of this material are described in detail in this paper.

to the boiling point, stirred mechanically for five minutes, and filtered hot. The elution is repeated once. Both elutes are combined and concentrated under diminished pressure at 40°C to a volume of 150 cc (3 cc per 100 Gm. of liver).

Different batches of the commercial liver extract contain 140 to 180 mg of total nitrogen, per 100 Gm of liver, and exhibit a biological activity of approximately 328,000 guinea pig units, per 100 Gm of liver². The light-brown colored ethyl alcohol elute, on the other hand, contains from 12 to 15 mg of total nitrogen per 100 Gm of the fresh liver from which it is derived, and a biological activity of approximately 164,000 guinea pig units. The evidence for the therapeutic efficacy of this elute in pernicious anemia is presented below.

Patient Date	J T 9/27/34	C H 1/16/35	F W 1/3/35	A T 10/1/35	J D 2/20/35	C H 2/1/35
Red blood cells in millions per c mm at beginning of experimental period	3.51	1.18	2.47	1.07	2.10	1.36
Red blood cells in millions per c mm at termination of experimental period	4.07	1.69	2.82	2.42	2.68	2.28
Reticulocyte peak, per cent	5.6	10.6	7.8	31.8	11.2	26.6
Length of experimental period, days	10	9	9	10	8	11
Total amount of fresh liver, from which administered extract, derived, grams	67	72	88	100	103	200
Total amount of nitrogen administered, milligrams	8.3	9.4	13.4	12	14	24

The starting point in the preparation is a commercial liver extract‡, in a concentration of 3 cc derived from 100 Gm of fresh liver. One hundred and fifty cc of this extract are dissolved in one liter of water. The solution is brought to pH 8 with NaOH and is then acidified to pH 6 with HCl. Fifty Gm of norit are added and the mixture is stirred mechanically for one hour, and filtered. The charcoal, washed repeatedly with water until the washings are colorless, is then suspended in one liter of 65 per cent ethyl alcohol, the mixture is brought

The elute was sterilized by boiling and was administered to the patients by intramuscular injection.

The preparation of the elute described above, and referred to in a previous publication¹, bears similarities to the procedure recently reported by Kyer³.

SUMMARY

Charcoal adsorption is utilized in the preparation of a partially purified liver extract that is therapeutically effective in pernicious anemia.

THE MECHANISM AND EFFECTS OF
ABDOMINAL COMPRESSION IN THE TREATMENT OF
PULMONARY TUBERCULOSIS*

BY BURGESS GORDON, M.D.†

IT is recognized that collapse therapy as induced by artificial pneumothorax, phrenic paralysis and thoracoplasty, is an important measure in the treatment of pulmonary tuberculosis¹. The immediate effects are decreased cough, expectoration and toxic manifestations with striking retrogression of the lesions in certain cases. Its value is promptly recognized in patients in whom artificial pneumothorax has been discontinued prematurely. In these the return of symptoms occurs almost coincidentally with the expansion of the lung.

Similar phenomena have been observed in pulmonary tuberculosis associated with abdominal tumors. A striking example is the abeyance of tuberculosis during the latter months of pregnancy and the subsequent reactivation of the lesion following delivery². A similar parallel occurs in tuberculous women with tumors of the abdomen, with an increase in the size of the mass, the tuberculous process becomes quiescent, but following removal of the growth, even under ideal surgical conditions, there is a reactivation of the infection.

The relationship between the structural development of the body and the activity of pulmonary tuberculosis has been considered since the earliest times. As for example the long type of chest and the scaphoid abdomen have been associated with the unfavorable cases, whereas the rounded or athletic type of chest, full or well-developed abdomen have suggested greater resistance to the disease. It has also been observed that pulmonary tuberculosis becomes aggravated in young women following a marked loss of weight and the discarding of corsets.

Evidently abdominal tumors and the well-developed abdomen exert an influence on pulmonary tuberculosis not unlike that of phrenic paralysis. However, in evaluating the effects contributing factors should be considered. As for example an individual of marked natural resistance would progress more satisfactorily than one belonging to a primitive race or one suffering from a metabolic disorder such as diabetes or hyperthyroidism. Likewise, no improvement would be expected in patients who have failed to observe a standard dietetic rest

regimen. With these factors recognized, the following hypothesis is proposed in order to discuss the relationship between abdominal conditions and the reactivation and spread of pulmonary tuberculosis: (1) That the disease is influenced favorably by the gradual increase of intraabdominal pressure which elevates and restricts the movements of the diaphragm and accordingly limits the vertical excursions of the lungs not unlike that in diaphragmatic paralysis, (2) that, with removal of the supporting influence of an abdominal tumor, there is an increase of respiratory activity, less rest for the lung, as would occur with the sudden regeneration of the phrenic nerve and the return of the diaphragm to normal function.

An attempt has been made in a series of 211 patients (collected cases) with fibroid pulmonary tuberculosis to imitate the mechanism of diaphragmatic elevation as it occurs in abdominal tumors. The procedure has been called "abdominal compression." It is accomplished by means of a special abdominal support, consisting of one or two cross-springs and a pad assembly which fit over the lower half of the abdomen, and is held in position by means of a back piece, straps and buckles*. The degree of compression regulates the level and movements of the diaphragm. The supports have been worn from two to thirty months day and night, except in intestinal tuberculosis and malnutrition when it has been necessary to remove them for short periods also in certain other instances in order to determine the possibility of retrogression occurring independently of treatment, eighty-two patients have been ambulatory practically throughout the period of observation, thirty-three have worked, the remaining number have had sanatorium care or the equivalent.

Symptomatic relief from dyspnea and dull, cough expectoration was the rule. Attacks of paroxysmal tachycardia were controlled in three patients, tympanitis and constipation improved in twelve, ninety gained in strength and generally "felt better." The relief of dyspnea and improvement in the lungs were quite constant in patients with an essentially fibroid type of disease and a well-developed abdomen. The unsatisfactory results, such as elevation of temperature with increased cough and dyspnea,

*The so-called two-spring model was used in patients confined to bed and in those with the flat type of abdomen; the single spring model was used in the pendulous type of abdomen. The supports are manufactured by the Geo. F. Pilling and Son Co., 3rd and Arch Streets, Philadelphia, Pa.

occurred in cases with acute extensions or soft caseating lesions

The physical examinations in the improved cases usually showed a decrease in the number of coarse râles, especially in the bases of the

FIGURE 1 A partially collapsed lung suspended by apical and diaphragmatic adhesions illustrating the ovoidal shape of the cavity during deep inspiration

FIGURE 2 Illustrating the effects of abdominal compression with elevated diaphragm and rounded cavity (for comparison see figure 1)

lungs, it was interesting that musical râles sometimes appeared and persisted but apparently were of no significance

The x-rays showed an average elevation of the diaphragm of 12 cm. Structural improvement occurred in forty-three patients (seventeen ambulatory, twenty-six at rest in bed), as evidenced by a decrease in the size of cavities or

their disappearance, and retrogression of the associated lesions. The largest cavity before treatment was 45 cm in diameter. Eleven were located in the upper one-third of the lung, five in the middle third, five in the lower third. They closed as follows: one in seven weeks, five in two months, three in three months and seven in five months. The supports were removed in four patients in whom cavities had diminished, an increase of cough and dyspnea followed almost immediately and in about three weeks the cavities returned to their former size. The supports were reapplied and the cavities again diminished in about two months. It was interesting that two apical cavities, which developed during artificial pneumothorax, closed after the

lung reexpanded and following abdominal compression. Twenty-six patients with cavitation and marked fibrosis were able to exercise without x-ray evidence of progression and they seemed to carry their lesions safely. This capacity to exercise safely was more remarkable than any changes that occurred in the lungs, for the reason that the patients had been regarded as suitable only for "cure" such as sitting in a chair.

The vital capacity studies in thirty-one patients showed at first a reduction of 10 to 20 per cent, which indicated a decrease in the available air space of the lung, due to a limitation in their vertical movements, with an increase of thoracic excursions, in twelve patients, there was a gradual return to within 5 per cent of the previous figure, in nineteen there was no appreciable change, but it was interesting that eight showed definite symptomatic improvement.

The respiratory rate was studied in thirty patients. In the majority there was an increase of two to five respirations per minute immediately following the application of the support, after wearing it for a few hours, the rate usually returned to the previous figure and breath-

ing became quiet. On slow walking, the rate was more frequently lower with the supports applied than without, on rapid walking the rate increased. The effects on dyspnea were often striking, some patients who were even short of breath while walking on level ground were able to walk up stairs easily.

In discussing the mechanism of abdominal compression as it concerns the tuberculous process, three factors may be considered: (1) the typical pathological development of pulmonary tuberculosis, (2) the possible changes in the lesions, due to deep, uncontrolled vertical excursions of the lungs, (3) pulmonary ventilation as it applies to the growth of tubercle bacilli.

The characteristic development of pulmonary tuberculosis, according to the x rays and post mortem examinations, begins at the apex of the lung. The lesion is essentially fibrotic. At the apex the process is typically fibrous, with a scattering of new tubercles to the lower lobe, the number of tubercles gradually becoming smaller at the base. The great amount of fibrosis at the apex is an indication of the chronic nature of the lesion and is in marked contrast with the tubercles in various stages of caseation or healing (fibrosis) at the lower levels of the lung. The clinical findings also indicate progressive involvement and correspond with the changes at postmortem. An important feature is the gradual downward extension of the riles, coincidentally with the formation of new tubercles. With clinical improvement there is a gradual disappearance of riles and x ray shadows beginning at the lower lobe, an indication of clearing of the lung fields.

The pathological development of pulmonary tuberculosis is so typical that one might wonder about the influences in its curious progression. One of these is the mechanical factor of respiration. This is characterized by more or less shallow rhythmical and equalized excursions of the lungs in different planes. An important feature is that the vertical movements are limited in strong, vigorous individuals and are governed largely by the diaphragm. Their value over deep inspirations has been pointed out repeatedly by women who voluntarily wear abdominal supports or corsets because they feel that the retained abdomen reduces fatigue and facilitates breathing. Except in singers who require slow prolonged expirations, the so-called 'abdominal' or 'diaphragmatic' type of breathing is not encouraged. Deep breathing is usually condemned in athletes because it is tiring and inefficient.

The effects of the deep, uncontrolled respirations upon the gross structures of the diseased lung are pointed out by Willauer.⁴ He has observed in thoracoscopic studies that a remarkable expansion of emphysematous blebs of the lung occurs during forceful expirations as in

coughing. Apparently a similar phenomenon occurs in bronchial strictures of the 'ball valve' type, associated with cavity formation, in which there is a tendency for air to be "trapped" in the adjacent parts of the lung, causing expansion, especially of thin walled cavities. The immediate changes in the size of cavities are sometimes shown in fluoroscopic studies of pneumothorax cases in which the lung is held out by apical and diaphragmatic adhesions. With forceful inspirations they become ovoidal in shape, then rounded as expiration occurs. Visualize the endless repetition of these phenomena of sudden expansions and contractions of blebs, cavities and bronchi in chronic pulmonary disease and the dangers to the lung will be appreciated. It is difficult to understand how a diseased part can withstand such changes indefinitely especially in regions unprotected by bone and muscle as in the apices and mediastinum.

The interesting studies of Walsh⁵ throw some light on the microscopic changes of the lungs that may be directly related to the mechanical factor of respiration. He has observed that the alveoli are of the same size throughout the lungs in the still born infant and in the infant two days old, that they are largest at the apex in the baby four months old, and in the adult they are definitely larger at the apex than at the base. He suggests that the enlargement may be due to greater respiratory activity of the apex. These differences in the size of the alveoli may be shown graphically in an experiment with a triangular sheet of rubber "punched" with holes (figure 3). It may be assumed that the vertex of the triangle represents the upper lobe of the lung, the 'holes' the alveoli. The vertex is held more or less firmly to imitate the apex of the lung as it is maintained in position in the thorax by negative intrapleural pressure, as the sheet is stretched, to correspond with the expansion of the lung during inspiration the 'holes' at the vertex become elliptical in shape by contrast with the more or less constant rounded "holes", or "alveoli" at the base. This parallel suggests that the weight of the lung and the action of the diaphragm play some part in developing larger alveoli at the apex. It may be significant that the permanent enlargement and the intermittent variations occurring with each inspiration, influence the development and progression of tuberculosis.

In considering the possibility that pulmonary ventilation favors the growth of tubercle bacilli, it is interesting to note the behavior of bacteria at different levels of the lung. It is recognized that pneumonia has a predilection for the lower lobe tuberculosis for the upper lobe, that the pneumococcus is aerobic, but optionally anaerobic and that the tubercle bacillus is distinctly aerobic. Pneumonia is frequently associated with arteriosclerosis and heart disease which

have a tendency to produce edema and passive hyperemia of the lower lobe, conditions which interfere with the aeration and circulatory activity of the part, further, that tuberculosis is so uncommonly associated with arteriosclerosis and heart disease as to allow the possibility of an antagonism between them

The relationship of anthro-silicosis to tuberculosis, on the basis of pulmonary ventilation, may also be significant. It is known that silicate causes marked pulmonary fibrosis and predisposes to tuberculosis and yet patients affected with this dust rarely die of the disease. It seems not unlikely that reduced aeration due to the destruction of myriads of alveoli interferes with the growth of tubercle bacilli.

SUMMARY

The study of signs and symptoms and various mechanical factors of respiration, suggests that the lesions of chronic pulmonary tuberculosis are aggravated by deep vertical excursions of the lungs, difficult expectoration and

the traumatizing action of cough. It appears that elevation of the diaphragm as induced by abdominal compression, controls the respirations and equalizes the movements of the lungs in different planes, thereby favoring rest for the diseased parts. The mechanism resembles bilateral phrenicectomy, with the advantage, however, that the propelling force of the diaphragm is preserved, which is of distinct value in expectoration. It is possible that reduced pulmonary ventilation tends to retard the growth of tubercle bacilli as in pneumoconiosis.

PEPTIC ULCER*

A Study of the Disease Before and After the Demonstrated Ulcer

BY MAURICE A. SCHNITKER, M.D., † AND WM. A. EVANS, JR., M.D. †

PEPTIC Ulcer is commonly considered a disease in which the ulcer in the stomach or duodenum is the essential lesion, without which the disease does not exist. However, there is another conception of the disease in which the actual ulceration is regarded as but one and perhaps not the most important or significant manifestation. Indeed, the disease may be present without any ulceration whatever for shorter or longer periods of time or it may conceivably run its entire course without the appearance of any ulceration. The purpose of our study has been to review the records of patients who had been followed for a considerable period of time during which an ulcer had been observed to develop and to compare the findings before and after the demonstration of the ulcer. According to our views the symptoms were such that we believe the disease was present from the onset of dyspeptic complaints and the appearance of the ulcer was but an incident in its course. As cavitation is but one lesion in the course of pulmonary tuberculosis, similarly we consider ulceration to be but a part of the picture in this disease. A search through the out-patient records of the Peter Bent Brigham Hospital revealed 1653 patients during the past ten years

in whom peptic ulcer was suspected clinically. Roentgen studies to establish the diagnosis were carried out in 1376. In 411 the examination was negative, and the majority of these patients were either not seen again or did not have subsequent roentgenological examinations. The diagnosis of peptic ulcer was confirmed at the first roentgenological examination in 934, the ulcer being found in the stomach in 106 and in the duodenum in 828. Thirty-one patients were found in whom one or more roentgenological examinations revealed no ulcer or ulcer deformity of the stomach or duodenum and in whom at a later date an ulcer was demonstrable. The records of these patients constitute the material for this study.

The basis for the diagnosis of an ulcer in a few cases was the actual demonstration of the ulcer itself at operation or as a crater by x-ray. More often, however, the diagnosis was based on the presence of a characteristic deformity which develops in the duodenum. This persistent deformity is generally regarded as direct evidence that an ulcer has been present. We have used the terms ulcer, crater, and deformity interchangeably in the discussion of the paper to indicate the occurrence of an ulcer. We have regarded the period up to and including the last examination showing no ulcer as the period "before" the ulcer. The period "after" the ulcer we have regarded as being that from the time of the first evidence of an ulcer as described.

above. Obviously there must exist between the negative and positive evidence a period of time during which the lesion develops. The manifestations occurring in this period cannot be classified as either before or after the ulcer and have not been considered in this study.

To include brief summaries of all thirty-one cases would add unnecessary length to the paper. In order to give the reader an idea of the type of case analyzed in making this study we are including only several examples. In the following case reports data that have not seemed pertinent have been purposely omitted.

CASE 1 S. S., a white male aged thirty-three in whom an ulcer was first demonstrated at the age of thirty-one. He had been having typical ulcer symptoms for ten years, i.e., epigastric distress coming on one to two hours after meals relieved by food and soda, and occurring in remissions and relapses. X-ray studies had been carried out in 1923, 1924, 1926 and 1928 and gave no evidence of ulcer. Findings somewhat suggestive but not typical of an ulcer were demonstrated in 1930. In 1933 a typical crater of the duodenum was demonstrated and confirmed on three subsequent occasions. Reexamination of all the previous films at the present time indicates thickening of the gastric rugae in 1924, 1926 and 1928 with an increase in thickening at the time the crater was demonstrated. The symptoms had remained the same for approximately ten years but became somewhat worse following the demonstration of the crater. There was thought to be a well marked nervous factor both before and after the demonstration of the crater. Gastric analysis in 1923 before the ulcer showed a range of the free acid from 52 to 108 degrees and of the total acid from 65 to 123 degrees. In 1933 after the demonstration of the crater the values for the free acid were 14 to 82 and for the total acid 11 to 114 degrees. The response to modified Sippy treatment was good before as well as after the demonstration of the crater.

CASE 2 C. H., a white female aged fifty-six who was moderately nervous. A duodenal ulcer was first demonstrated at the age of forty-eight. The symptoms had been of four years duration and were somewhat atypical for an ulcer. The first gastrointestinal x-ray studies in March 1924 showed some spasm in the stomach and inconclusive findings in the duodenum. A second x-ray study one month later showed a hypertonic stomach and findings in the duodenum less suggestive of an ulcer than before. A third x-ray study in 1925 was entirely negative. A roentgenogram in 1926 was also interpreted as essentially negative. A fifth examination in June 1926 showed an hourglass deformity of the stomach and a constant irregularity of the duodenal cap typical of a duodenal ulcer. There was no change in symptoms before or after visualization of the duodenal lesion. A gastric analysis in 1924 before the ulcer (one specimen) showed a free acid value of 30 and a total acid value of 64 degrees. In 1926 with the demonstration of the ulcer the values were 5 to 50 and 30 to 65 respectively. The response to treatment with diet and powders was poor before the ulcer was demonstrated. An operation after the ulcer was found failed to give relief.

Certain objections to the significance or actual existence of such a group immediately arise. The small size of the group would appear to be due in part to the fact that patients did not

present themselves until their disease had been present for a considerable period of time and was then well advanced, and in part to the fact that some patients with negative roentgenological examinations were not followed further and were dismissed as having a disorder of no importance. The possibility that these patients simply represent ones in whom an ulcer was overlooked at the first x-ray examination can not be easily denied and this may be true particularly in a few cases in which the initial examination was done before the present accuracy of diagnosis had been attained. A further objection is the possibility that during the apparent ulcer free phase of the disease, a crater may have been present at some point in the stomach or duodenum where it could be demonstrated only with great difficulty if at all and that the appearance of a demonstrable ulcer was no more than the appearance of a second ulcer in a location more favorable for demonstration. It is well known that small ulcerations on the posterior wall of the stomach are particularly difficult to demonstrate even with the newer method of relief study of the mucosa and their presence cannot be readily denied without gastroscopic confirmation. However, where a number of our patients were submitted to repeated examinations which were negative and then, with the same technique carried out in the same department, a crater or deformity was demonstrated at a later date, we feel that the ulceration actually developed in the interim. A final possibility is that these patients had previously had peptic ulcers which at the time of the negative examination had healed without a deformity and which later recurred. This possibility obtains particularly in the case of gastric lesions. Thus Nicholas and Mounieriff have pointed out that in the recurrence of a gastric ulcer, symptoms may reappear before a crater becomes demonstrable roentgenologically. Notwithstanding these alternative explanations which quite possibly represent the facts in a few cases, we have assumed the group as a whole to consist of patients who were observed at a period in their disease before any ulcer had appeared. In a few cases the films are available for reexamination and confirmation of the presence or absence of an ulcer so far as this is possible.

The thirty-one cases fall into four groups. The first of sixteen patients consists of those in whom the first Roentgen studies were entirely negative so far as the stomach or the duodenum was concerned and in whom a duodenal ulcer was demonstrated subsequently. The second group contains two patients in whom a gastric ulcer appeared. In the third group are two patients in whom the evidence is in part surgical. In one two exploratory laparotomies by experienced surgeons gave no evidence of a peptic

ulcer although the stomach and duodenum were carefully examined on both occasions, a duodenal ulcer finally being demonstrated roentgenologically four years after the last laparotomy. In the other, four roentgen examinations over a period of five years failed to reveal a crater or the deformity of one, while the presence of a duodenal ulcer was later established by laparotomy. The final group of eleven patients consists of those in whom the first barium studies were regarded as doubtful because of a transient deformity or irritability of the duodenal cap. In these patients, no crater or constant deformity could be made out in the initial examinations although a typical duodenal ulcer was demonstrable at a later date. In retrospect, evidence in these cases would indicate that the lesion present at the time of the early examinations was a duodenitis.

In studying the records of these patients an attempt was made to compare the symptomatology of the disease before and after the appearance of the ulcer. Particular attention was paid to the nervous make-up of the patient, to the character and severity of his symptoms, any evidence of bleeding or perforation, and the response to treatment. When possible, comparison was made of the acidity of the gastric juice in the two periods. In addition, a note was made of manifestations which may be associated with the ulcer syndrome², i.e., inflammatory lesions in the gastrointestinal tract (gastritis, duodenitis, colitis) and disturbances of motility (cardiospasm, pylorospasm, diarrhea and constipation). In some patients, the symptoms appeared to arise in large part, if not entirely, from one or another of these associated lesions at the time when no ulcer was demonstrable.

DISCUSSION

It is not unusual for a case to come to necropsy with a peptic ulcer or the scar of one, the patient never having had symptoms suggestive of that disease³. Similarly, in the course of another study we have recently observed three patients with Roentgen evidence of a penetrating ulcer who had not had symptoms of their disease for months. It is unusual to observe patients with a crater without symptoms for the obvious reason that in the absence of symptoms Roentgen studies are not made. That an individual may have symptoms typical of ulcer distress without a demonstrable crater is generally recognized. Alvarez⁴ has given the name "pseudo-ulcer" to such cases. In some of these individuals after a period of such symptoms an ulcer develops. These facts seem to indicate that there is no necessary correlation between the presence of a crater and the peptic ulcer symptomatology. The few writers on this phase of the disease have not stated what the time

interval of symptoms may be before the ulcer develops, although Noipoth⁵ reported three cases with symptoms for four, seventeen, and nine years respectively before the ulcer was demonstrated. Somewhat similar to the studies we have carried out, the first x-ray examinations in all three of his cases showed thickened rugae and no ulcer, and from five to sixteen months later, a second examination revealed a duodenal ulcer in two patients and a gastric ulcer in the other. In our series of thirty-one cases we found the period of symptoms before the ulcer was demonstrated to be from one to twenty-five years. The average for the group was 9.1 years but in the majority it was twelve to fifteen years. The time interval between consecutive x-ray examinations varied a great deal, the probable explanation being either that the physician minimized the symptoms or that the patient was reluctant to have another barium study if the first was reported negative. In ten of the thirty-one cases there was more than one negative Roentgen examination before the demonstration of the ulcer, one case had had five negative reports over a period of seven years before the ulcer was seen.

This group of thirty-one cases was analyzed to determine whether these individuals differed in any respect from the average patients with an ulcer. There were more males than females, a sex incidence not unusual for ulcer disease. In twenty-nine the ulcer was located in the duodenum and in two it was in the stomach. Most of the individuals were in the later decades of life when the ulcer became manifest. The range of age was eighteen to sixty-nine, nine of the patients being over fifty years of age and nineteen over forty. These patients appeared to be of about the same age at the time the ulcer developed as is the case with average groups of patients with ulcer.

In the records of twenty-five patients when a statement had been made, there was distinct nervousness in twenty. The frequency and degree of nervousness in this group seemed to be the same as in a group of average ulcer cases. This seemed of interest inasmuch as one might be tempted to explain the existence of such a group on the basis that these individuals were perhaps more nervous and meticulous and hence would seek medical advice sooner than do most persons.

The cases were studied further to compare the findings before and after the demonstration of the ulcer. One of the most striking features was the absence of appreciable changes in symptomatology with the presence of the crater or deformity. In a few cases there were other disorders of the gastrointestinal tract, but even then, there were additional symptoms in most cases quite typical of ulcer distress. In four cases the symptoms were somewhat atypical but

they were of the same character after the ulcer developed. In one there was an irritable colon and in another gallbladder disease which may have contributed to the bizarre complaints. In most of the individuals the symptoms were of the same character and severity throughout the course of the disease. In three there was an increase in intensity at the time the ulcer was found. In two cases the symptoms were actually more mild at the time an ulcer was demonstrated and so far as we could tell this was not the result of previous symptomatic treatment. There appeared to be a high incidence of night pain, its presence occurring in seventeen of the thirty-one individuals. In eleven of the seventeen this type of pain was present before the ulcer was demonstrable. If the universal teaching is accepted that night pain is more characteristic and more commonly found in duodenal than in gastric ulcer, the high incidence of night pain would appear to be due to the fact that twenty-nine of our cases were of duodenal ulcer.

Compared to larger groups of average ulcer cases there did not appear to be any appreciable difference in the frequency of nausea, vomiting, bleeding, or perforation. It is well known that an x-ray examination of the stomach or duodenum often does not reveal an ulcer at the time of bleeding and it may not be found for some time after the bleeding has ceased. Crohn, Weiskopf and Aschner⁶ consider such cases of so-called "essential" hematemesis which later have an ulcer to be in the "regressive" phase of the disease. However, it is well known among gastroscopists (*Korbsch*) that bleeding may occur from small areas of inflammation in the mucosa where no ulcer is present. Six of our cases had evidence of slight bleeding at a time when no ulcer was demonstrable by Roentgen examination. After the ulcer was present there was additional bleeding in two of these and in three others. The occurrence of bleeding in a total of nine cases (twenty-nine per cent) is not an unusual figure and agrees very well with the studies of Emery and Monroe⁷ of two much larger series of cases where the incidence of bleeding was found to be 26.7 and 34.8 per cent respectively.

Another point of interest was a comparison in the level of gastric acidity before and after the appearance of the ulcer. In nine of the cases an analysis with the Ewald meal had been done before the ulcer appeared and in four of these the free acidity was high, i.e., in at least one specimen it was over 50°. In one case the free acidity was as high as 108°. In one case there was no free acid present in the gastric contents after the Ewald meal, the response to histamine was not tried. The gastric analysis in these nine cases after the ulcer was present

showed no appreciable difference from the previous tests in seven, in one case the values were slightly higher and in the other both the free and total acid levels were definitely lower. In the remaining twenty-two cases, four had tests only before and nine only after the appearance of the ulcer. In nine of these thirteen the acidity was high and in four it was normal. In the total group of twenty-two patients in whom a gastric analysis was carried out, there were eight with a normal acidity, i.e., $P.A. 5-30^\circ$.

In reviewing the available films of these cases, we attempted to determine the presence of thickened gastric rugae. In 1829 Cruveilhier⁸ reported chronic peptic ulcer as an entity distinct from cancer of the stomach and chronic gastritis. He gave a clear anatomic and clinical description of the disease suggesting as a primary lesion preceding inflammation. More recently that association has been stressed particularly by Konjetzny.¹⁰ With the newer methods of gastroscopy, thickened rugae have been found to be a characteristic feature of the gastritis of ulcer disease. This thickening of the rugae can be estimated from a film of the barium filled stomach. However, from our studies we feel one cannot make a diagnosis of ulcer disease from the presence of thickened rugae alone. We found that the average trend in about half of the cases was a slight but definite increase in the thickness of the rugae up to the time of the demonstration of the ulcer. This definite progression occurred in twelve of the twenty-five cases in which the films were available, in three others such an increase was questionable. In four the rugae were slightly thickened at the first examination and they appeared unchanged at the time the ulcer was seen. In four other cases the rugae appeared normal throughout all the x-ray studies. It was rather striking that in two cases the rugae were definitely less tortuous and thickened at the time of the ulcer than on previous films.

Since most of the patients were given a bland diet, alkaline powders and milk on some schedule for the alleviation of symptoms even when the x-ray was negative for ulcer we were able to draw some conclusions as to the response to symptomatic treatment both before and after the ulcer was demonstrated. In many instances, of course a more strict regime was outlined and followed after an ulcer was found. Grading the response to treatment as poor, fair, and good we found that before the ulcer, five did poorly, six did fairly, and eleven responded well. In nine cases there was no note from which to judge the response to treatment. After the ulcer appeared and often a more strict regime was instituted one did poorly, thirteen did fairly and fourteen had a good response to treatment.

In three cases this information was not available. Of the twenty-two cases then, in which we have data before and after the ulcer, there was a better response to symptomatic treatment in four, in two it was worse, and in sixteen the same with the demonstration of the ulcer. Similarly, as there was little change in symptomatology and no appreciable difference in gastric acidity, so there was also little variation in the response to treatment before and after an ulcer was found to be present.

CONCLUSIONS

A study has been made of thirty-one patients with peptic ulcer who were seen in the period of the disease when no ulcer was demonstrable. A comparison was made of the findings before and after the demonstration of the ulcer.

There was no striking change in the character or severity of the symptoms with the demonstration of the ulcer. Likewise there was no constant variation in the gastric acidity, in the incidence of bleeding, or in the response to symptomatic treatment in the two periods of the disease.

Roentgen evidence of inflammatory lesions (gastritis and duodenitis) was present in the majority of the cases before the demonstration of the ulcer and later there was generally an increase in the severity of these lesions. In some cases however, no evidence of inflamma-

tion was obtained either before or after the ulcer was seen. We do not believe that a diagnosis of peptic ulcer can be made on the basis of tortuous and thickened rugae alone.

These findings give support to the view that an ulcer of the stomach or duodenum is simply the local manifestation of a more general disorder. They also confirm an impression that a crater, as demonstrated roentgenologically, is but an incident in the course of the peptic ulcer disease.

We wish to acknowledge the kind help given to us by Dr W W Vaughan from the Department of Roentgenology in reviewing the films in this study.

VERMONT STATE MEDICAL SOCIETY

DERMOID TEETH IN THE EXTERNAL AUDITORY CANAL, WITH COMMENTS ON TERATOMAS AND DERMOIDS IN GENERAL*

BY GEORGE G MARSHALL, M D †

BECAUSE of the rarity of dermoid teeth being found in the external auditory canal, and because of the mystery and interesting theories of the production of dermoids and teratomas, associated as they are with the disorderly cell life in their production, as well as that of malignant tumors, I have chosen this as my subject with a report of three cases, the first of which recently came under my observation. One other case is reported by Becco of Argentina⁵, and one of simple dermoid in the auditory canal is reported by Adam and Gilmour of Glasgow⁴.

CASE 1 Report of my case. R C, aged fifteen, first seen September 6, 1934. Referred by Dr Briggs of Brandon, Vt., because of increasing deafness of the right ear. There had been no pain or aural

discharge, but the patient had noticed an obstruction in the external auditory meatus. On an office examination there appeared to be an exostosis, covered by a cutaneous membrane, filling the aural canal so completely that only a thin instrument could be introduced beside the bony growth. On October 8 he entered the Rutland City Hospital for removal of the growth. Under ether a more thorough examination being made, to determine the supposed attachment, it was noticed that the tumor was movable. A small hook was then passed along the side of the canal, until it engaged back of the tumor, when the tumor was extracted by gentle manipulation, and to our surprise on examination it proved to be a molar tooth. Then on looking into the canal, to determine its condition and especially that of the drum, another similar tumor was seen deeper in the canal. This one also was movable and had a thin epithelial covering. The hook was then worked back of this growth and extracted as in the first case. This tumor also proved to be an imperfect molar. After cleaning the canal of what appeared to be sebaceous material, the drum was found to be normal. The canal showed some pressure necrosis, but there were no sinuses. After a week the parts had regained a healthy appearance, with restoration of normal hearing. Radio-

graphs of the jaw by his dentist, Dr William Pond showed the right lower third molar missing and the left lower third molar lay horizontal and un-erupted. (Slides of the dermoid teeth shown Fig ure 1)

Photo of extracted teeth from Case 1

CASE 2 Reported by Raul Becco Chief of the Service of the Otolaryngological Department of the Italian Hospital of Argentina. The following is taken from Becco's report. A boy born in Florence, Italy who, at the age of fifteen first noticed an obstruction in the left ear for which he consulted an aural surgeon was informed that he had an exostosis in the aural canal, and operation for its removal was advised. Since there was no discomfort other than a slight loss of hearing operation was declined. Four years later in 1913 he emigrated to Buenos Aires where he had increasing trouble hearing became more defective and he had periods of purulent fetid discharge with frequent pain in the ear and severe intermittent headache. For these symptoms he visited several service hospitals and at each operation was advised. In 1928 he first consulted Dr Becco who found what he thought was an exostosis nearly filling the auditory canal complicated by a purulent discharge. The patient now entered the Italian Service Hospital and on March 5 Dr Becco operated. Incision was made postaurally and it was planned to chisel away part of the bony canal, but the tumor was found to be movable and was easily extracted with forceps. On examination it proved to be an imperfect molar. There were no sinuses in the canal. He made a good recovery but with defective hearing owing to the injured drum from long pressure and secondary infection. Dr Becco in his report says that he has searched the medical literature extensively and has not found a similar case recorded although there were many references to dermoid cysts in the outer ear and mastoid.

CASE 3. Reported by Adam and Gilmour. They preface their report by saying "The rarity of this sort of tumor is sufficiently shown by the fact that it is not mentioned in aural textbooks but it has pathological implications that render the case worthy of record."

They report as follows. A woman aged sixty five first seen in 1928. She had known of a growth in her right ear for eighteen years. At this time there was no pain or discharge but the hearing was very defective. In October 1929 she was having pain in the ear, giddiness and purulent otorrhea. She was now taken to the Stobhill hospital, and after the usual postauricular incision the meatal wall was split and a dermoid tumor delivered. The pedicle, which was attached behind the angle of the jaw, was easily severed. The postaural wound healed by first intention and the suppurations from the middle ear ceased. The tympanic cavity was not visible, owing to the changes brought about by pressure of the tumor. The dermoid was covered with epidermis and was so firm as to be at first mistaken for an osteoma.

In Adams opinion this was a dermoid growth from the first branchial cleft.

Misplaced teeth have often been found in the antrum, more rarely in the orbit, and dermoids containing teeth, together with recognized tissues from any of the three germ layers are found in many parts of the body.

The first case here reported is I believe the first instance of dermoid teeth being found in the aural canal recorded in American literature. The second is the only recorded case that I have been able to find in foreign literature. The third case, reported from Edinburgh, is similar, but no teeth were found in the dermoid. It is possible that some cases diagnosed as exostosis may have been dermoids.

CONSIDERATION OF TERATOMAS AND DERMIDS IN OCEANAL

Definition. A teratoma is a tumor composed of tissues and complex organs derived from more than one germ layer and may be located in parts foreign to the tissues of which it is composed. A dermoid is an imperfect teratoma composed chiefly of the ectodermal germ layer. The tissues in either case are disorderly arranged and without physiological purpose composed of either mature or embryonic cells, the latter showing a strong tendency to malignancy.

History. In the Middle Ages a dermoid was thought to be a malformed fetus, and to be the judgment of God for immoral practices, but in 1789 Baillie reported an ovarian dermoid in a virgin girl, aged eleven and from then more rational explanations were attempted.

Etiology. While there is no proved cause for the production of teratomas and dermoids there are a few theories that seem acceptable. First. The defective closure of certain embryonic clefts with inclusion of cells from the ectodermal layer, this takes place in the fifth or sixth week of embryonic life. The branchial clefts of the neck are one of the most common sites, and faulty closure of the first branchial cleft offers the best explanation of the dermoid teeth in the cases here reported.

Inclusion error of the neural groove with infolding of the ectodermal layer may give rise to spinal dermoids. Fraser of Edinburgh reports such a case.

The following paragraph will help to clarify the second theory, that of misplaced blastomeres. A blastomere is one of the cells resulting from the first few divisions of the fertilized ovum. Those resulting from the earliest division are called totipotent, since they can produce any tissue of the body. They differ from

Dermoids have been reported as having been found in the following regions, orbit, cornea, conjunctiva, brain, frontals, parietal bone, anterior wall of the rectum, pelvic connection, iliacus, pancreas, nose, terminal phalanx of the thumb, sacrococcygeal region, mammary umbilicus, vaginal canal, round ligament, wall of the Fallopian tube, ovary, scrotum, perineum, neck, ears, at rim of plural cavity and floor of the mouth.

blastomeres of further divisions, which are called multipotent, and evolve many tissues, though not all, and finally cells from further divisions are called unipotent, because they are capable of building but one kind of tissue⁸. According to this theory one of the blastomeres becomes misplaced during the embryonic period and usually remains dormant until some time in adolescent or adult life if not permanently. The complexity of the teratoma is determined by the type of blastomere displaced. Ewing says "The possibility must also be considered that the formative capacity of anatomically pure germ layers may not always be restrained within the rigid limits formerly set"⁹.

Third theory Aberrant or wandering germ cells in the developing embryo are found widely scattered, the length of the embryonal entoderm, and these aberrant cells are thought to be one of the most frequent causes of teratomas, especially those occurring in the sex organs. The delayed development of these undifferentiated cells should not be considered strange since we have normal examples of delayed cell changes, like the successive eruption of teeth, the activity of hair follicles at puberty, and other equally familiar cases.

There has been much research in an effort to determine why certain groups of cells start on an uncontrolled proliferation in the production of benign and malignant tumors. There is an inherent tendency in all cells to multiply, and the tailed cell or spermatozoa, discovered in 1677 by Hamm, but whose function was not proved until 1844 by Wagner and Koelliker is not the only means of cell fertilization or division.² For example, Loeb induced starfish eggs to segment by adding soda water to sea water, called shock fertilization, and later Battalio induced complete embryogenesis in frogs' eggs by pricking them with a glass stylet dipped in the frogs' blood.

One of the most interesting theories of cell multiplication is known as Parthenogenesis, a normal process of automatic cell proliferation in the lower forms of vegetable and animal life. An example is that of the sea urchin's egg. More speculative is the theory of tissue cell fertilization by conjugation with leukocytes (Kefts). Trauma is probably one of the most frequent causes for activation of these misplaced cells. Ewing says, "There is abundant evidence that not only chronic irritation, but that single or multiple direct injuries may excite malignant growths in predisposing unstable cells"¹⁰. Recent experimental work by Crile⁷ reported in the *American Journal of Surgery*, in May, 1931¹⁰, confirms that trauma may excite pathological growth in normal cells. He says "Cancer cells are normal cells so structurally altered by mechanical, chemical or radiant energy that they

are partly or wholly bereft of their normal function, and their power to multiply is correspondingly increased". He adds, "A cancer cell is an injured normal cell".

These are a few of the many interesting theories advanced to explain the abnormal growths known as teratomas and dermoids, as well as that of malignant cell activity.

Diagnosis of teratomas and dermoids is often difficult, the history and physical appearance, together with radiographs will in some cases be sufficient, but often the true nature cannot be determined until operation and microscopic section.

Prognosis Dermoids and teratomas continue to increase in size by cell proliferation, and the accumulating debris from the epithelial layer, so that by simple pressure they may encroach on vital organs, causing great distress and may even prove fatal. Dr. S. W. Harrington of the Mayo Clinic reports cases of mediastinal teratomas that by pressure invaded the lung causing dyspnea, and the expectoration of hair from the ruptured teratoma. In one of his cases the mediastinal teratoma penetrated the diaphragm involving the liver.⁷

Both teratomas and dermoids are prone to infection. Finally, a teratoma, especially of the embryonic type, may become malignant, forming metastasis. Gibson and Arnold⁹ report a case of metastasis into the neck from a malignant teratoma of the testicle, the metastatic tumor being found before that of the original malignant teratoma.

Treatment Cases like the three here reported obviously should be operated early for the preservation of hearing, the prevention of pressure necrosis and late infection. The early, thorough operative removal of teratomas and dermoids should be advocated in all cases, since there are these three dangers which have already been mentioned under the head of prognosis, namely, pressure necrosis, secondly, infection and thirdly, malignancy.

MISCELLANY

VERMONT DEPARTMENT OF PUBLIC HEALTH

DECEMBER 1935

The following communicable diseases were reported to the office of the Department of Public Health during the month of December: chicken pox 501 diphtheria 4 measles 534 German measles 2 mumps 173 poliomyelitis 4 typhoid fever 2 scarlet fever 57 undulant fever 2 whooping cough 191 and tuberculosis 10.

The Laboratory of Hygiene made 1503 examinations, the details of which are as follows:

Examinations for diphtheria bacilli	92
" " Widal reaction of typhoid fever	30
" " undulant fever	43
" " gonococci in pus	131
" " tubercle bacilli	141
" " syphilis	56
" of water chemical and bacteriological	5
" water bacteriological	235
" milk market	117
" milk submitted for chemical only	1
" milk, submitted for microscopical only	8
" foods	3

Examinations of drugs	0
" for courts autopsies	3
" courts miscellaneous	9
" miscellaneous	63
Autopsies to complete death returns	3

The Director of the Division of Venereal Diseases reports twenty-nine cases of gonorrhea and forty-one cases of syphilis made to this Division in December. Eight hundred and four Wassermann outfits had three hundred and forty-four slides for gonorrhea were distributed from this Division.

The After-Care Nurses of the Infantile Paralysis After-Care Division made eighty home visits calling on eighty-two patients. Five patients were admitted to the Audubon Hospital and six patients were discharged. Three patients were admitted to the Children's Hospital and one patient was discharged. Thirteen pieces of apparatus were fitted, two pieces of apparatus were repaired and six orthopedic corrections were made to shoes. The Vocational Worker of this Division reports sales made amounting to \$49.50.

Five towns of the state were visited by the State Advisory Nurse of the Public Health Nursing Division. Part of the nurse's time was devoted to the WPA project, and the making of plans for a second project. Nine hundred and thirty-three notifications of birth registration and three hundred and forty-one pamphlets were mailed out in December.

MEDICAL PROGRESS

PROGRESS IN UROLOGY, 1934

BY FLETCHER H. COLBY, M.D.*

CANCER of the bladder has always been a difficult problem. Through the work of the Carcinoma Registry of The American Urological Association sufficient important data have been collected during the last seven years to warrant a review of the 902 reported tumors. The committee on carcinoma registry has studied this large series of cases and has made available many valuable facts in its report.¹

These neoplasms were considerably more common in men than women. The incidence was 76.25 for the male and 23.75 for the female.

Over half of the cases registered occurred between the ages of fifty and sixty-nine with the age peak between sixty and sixty-four. In only five patients were tumors present before the age of thirty and but ten after eighty years of age. It has been said that tumors in the extremes of life, the very young and aged are of higher malignancy than others but the material of the registry does not tend to bear this out.

A study of the occupations of the patients included in the report revealed no significant feature except for the occurrence of sixteen epithelial tumors of the bladder among aniline dye workers. The high incidence of bladder cancer among individuals exposed to the aniline compounds has been a recognized fact for many years. Except for these cases no facts presented themselves which could be interpreted as causative factors in the etiology of carcinoma of the bladder.

Certain facts relating to some of these tumors suggest that they originate in the basal layers of the epithelium, about the terminal blood vessels, and they may reach a considerable size before the superficial layers of the epithelium are destroyed. These findings also suggest that some bladder tumors may originate as a result of certain carcinogenic agents circulating in the blood, thereby affecting the entire bladder mucosa. These facts apply more particularly to the aniline tumors, but the committee found that the distribution of both single and multiple tumors, as noted in the registry, appeared to follow closely the vascular supply of the deeper

*Colby Fletcher H.—Assistant Visiting Urologist, Massachusetts General Hospital. For record and address of author see "This Week's Issue," page 217.

layers of the epithelium. The high incidence of multiple tumors (29.2 per cent) was also considered suggestive in this respect.

A study of the situation of these tumors showed that the majority (76.6 per cent) arose from the lateral walls, trigone and bladder neck. This fact is of great importance since only the remaining 23.4 per cent of the growths involved portions of the bladder which would permit wide surgical excision without damaging the urethra or one of the ureters. This high percentage of invasion of the less mobile and less accessible portions of the bladder constitutes one of the chief difficulties in adequate treatment of bladder cancer.

Correlation of the location of the tumor and the degree of malignancy brought out a significant fact. Tumors involving the vault were usually highly malignant (75 per cent grades III and IV). The incidence of metastasis for this location was also greatly increased. Tumors which arose from the lateral wall, trigone or bladder neck were less likely to be so highly malignant (53.4 per cent were grades I and II), and in this type of growth the percentage of five-year cures was considerably higher, as contrasted with vault tumors. With the exception of the vault tumors, this series showed that the location of the primary growth had little apparent relation to the prognosis.

Multiple tumors were found likely to be of lower malignancy than single tumors. In many instances of recurring tumors it is believed that the new tumors represent true new growths originating in multiple foci in the bladder mucosa rather than that they are recurrences. Some of these multiple tumors were proved to be clinically malignant although histologically apparently benign.

Metastasis probably occurs in bladder tumors more frequently than is generally supposed. Approximately 10 per cent of the cases in this series showed metastases to the bones, lungs, regional lymph nodes and other locations. The incidence is undoubtedly higher than this since many of the cases included in the series were not examined for metastases. Other writers speak of this.^{2, 3}

The registry adopted this simple classification of the epithelial tumors:

- I Papillary carcinoma
- II Infiltrating carcinoma
- III Unusual types of epithelial tumors
 - a. Adenocarcinoma.
 - b. Colloid carcinoma.
 - c. Adenoma malignum (intestinal origin)

The tumors were graded on the basis of Broder's classification, and it should be noted that the histologically benign papilloma is included in the grade I papillary carcinoma group.

That there is still a considerable delay between the onset of the initial symptoms and

sufficiently adequate examination to make a diagnosis of bladder tumor, is quite evident in this series. In nearly one half of the patients (48.3 per cent) the diagnosis was delayed for more than one year. Only 10.8 per cent were completely examined and the diagnosis established, within one month of the initial symptom. Even so striking a symptom as hematuria was disregarded for over one year in 46.45 per cent. In other words, the importance of hematuria has not yet been appreciated by the layman or the doctor.

The standard methods of treating the cases in this series were resection, fulguration and radiation. The committee found it impossible to compare the results obtained from the various kinds of treatment. Of 349 cases observed five years or more, 33.24 per cent were alive at the end of five years.

Stone formation in the urinary tract is a subject of surpassing interest. The disease was prevalent in the human race centuries previous to the most ancient medical records and the earliest urinary calculus was discovered in Egypt among the bones of a boy of about sixteen. The grave is said to have belonged to the middle or late-middle prehistoric age some generations at least before the advent of Meres, the first Dynastic king (about 4800 B.C.).⁴ Analysis and study of this stone demonstrated that it was similar to those of the present day which occur in certain parts of India. Is the etiology of stone shrouded in mystery now as much as in the day of this earliest known sufferer, or has progress been made in solving this very important problem?

Stone was very common in Europe during the Middle Ages and until the beginning of the 19th century. Children were particularly afflicted with the disease. Still, in some parts of the world, particularly Southern China and certain portions of India, urinary calculus has a very high incidence. As better food conditions prevailed in Europe this tendency to stone formation declined. Vitamin deficiency, then, played an unquestioned part in stone formation. It is difficult, however, to account for all instances of the disease on this basis, convincing as are certain of the facts brought out by the artificial production of calculi in laboratory animals which have been kept on low vitamin diets.

Again, urinary stasis and infection have a bearing on stone production. The incidence of calculi is considerably higher when the normal flow of urine is obstructed, such as in the various congenital abnormalities of the urinary organs, hydronephrosis, horseshoe kidney and developmental obstructions of the urethra. Vesical calculi are frequently present in the bladder obstructed by the enlarged prostate, and stones are often found in bladder diverticula. In these conditions obstruction appears to be an obvious factor in stone formation.

Infection is difficult to evaluate as a cause of lithiasis. It is undoubtedly true that many stones develop in a sterile urine. Often it is impossible to be sure whether infection was present before a stone formed, or resulted from stasis as a result of the presence of a calculus. Certain types of infections do definitely increase the likelihood of stone. Organisms that split urea such as *Bacillus proteus* have been known for a long time to favor stone formation.

Disturbances of body metabolism cause stones to form in the urinary tract. This has been clearly shown in cystin stones from faulty metabolism of sulphur and in the calcium and phosphatic stones so frequently present in patients suffering from a deranged calcium metabolism associated with parathyroid disease. On the other hand, evidence of disturbed metabolism is entirely lacking in the ordinary individual with urinary tract stone.

Stone formation is now the subject of careful study by the internist, chemist and urologist and, although the problem is far from solved, progress is being made each year as new facts and theories accumulate.

The subject of *renal infarcts* is one which has received comparatively little attention in the literature although it is our impression that it is not a rare condition. Two such cases have been recently observed on the wards at the Massachusetts General Hospital. Frequently an accurate diagnosis is not reached until the kidney is exposed at operation or autopsy, as was true in a recently reported case by Saelhof¹ of infarction of the left kidney with thrombosis of the renal vessels. In this instance the symptoms of acute, severe pain in the renal region were pronounced, a moderate leucocytosis was present, the urine was normal save for a trace of albumin, and intravenous pyelography revealed considerable impairment of the function of the affected kidney. The true condition was recognized at operation when the kidney was removed. This patient recovered but died in three and a half months from thrombosis of the coronary artery and multiple thrombi of the pulmonary vessel and pulmonary infarcts.

The above case is cited as being typical in so many respects of renal infarction. That one vascular accident may rapidly follow another in those patients was evident in a recently studied case at the Massachusetts General Hospital. The patient was a young woman with chronic valvular heart disease who entered the hospital complaining of sudden severe pain in the region of the kidney. Signs and symptoms which were similar to those of the previously mentioned patient were present and this patient died suddenly about three weeks later from probable thrombosis of the vessels supplying the brain stem.

A very good review of this little mentioned subject of renal infarcts was presented by Bar

ney and Mintz² who studied the autopsy reports of 143 cases of the condition at the Massachusetts General Hospital. That such cases are usually seen on the Medical Service was evident from the fact that 117 or 83 per cent of these patients were admitted to the medical wards. Almost all of them were suffering from acute or chronic heart disease, many had advanced arteriosclerosis.

Study of this large series of cases brought out certain facts. All ages were represented from a boy of six to a man of seventy seven the majority occurring between the ages of thirty and fifty. More than half (68 per cent) of these patients had shown no rise in temperature. Examination of the urine in about one third of these cases failed to reveal any abnormality and in but four had there been gross hematuria. Urinary symptoms for the most part were entirely absent. Nausea and vomiting were symptoms in a small number (8 per cent), and none complained of persistent or excessive diarrhea although such symptoms were reported as prominent in renal infarction by other observers. It is surprising that over half of these patients (64 per cent) gave no history of pain or tenderness at any time, although multiple and large infarcts were found present. The authors conclude that while total infarction of the kidney may be associated with pain and tenderness, patients with extensive infarcts may be entirely free from such symptoms.

The important relationship which cardiac pathology bears to renal infarction was evident from the fact that only six (4.4 per cent) of the 136 cases so studied gave evidence of normal hearts. Most of the patients exhibited lesions of the valves or myocardium of long standing. Endocarditis, therefore acute or chronic, usually associated with cardiac hypertrophy and dilatation, was considered the most important factor in the production of renal infarcts. The portions of the vascular system (excluding the heart) most often involved were the renal arteries, common and external iliac arteries and veins, femoral vessels, abdominal aorta and in inferior vena cava in order of frequency. Other vessels were occasionally occluded, such as the mesenteric or splenic artery, the hepatic artery and the large vessels supplying the extremities.

Infection (presumably blood stream) was demonstrated in about half of these cases and was considered of more frequent occurrence than this since many of them dated back to the years of less reliable bacteriological methods. Streptococci usually viridans, were cultured in 72.7 per cent and staphylococci in 18.1 per cent.

The prognosis of renal infarction is considered necessarily serious because of the great probability of continued vascular accidents. The lack of complete study of most of these patients by intravenous and retrograde pyelography adds but little information which is helpful in establishing the diagnosis. A more general rec

ognition of the condition combined with recent methods of study should considerably improve our ability to make the diagnosis of renal infarction.

"If one has an opportunity to observe many cases of chronic Bright's Disease, he will occasionally be surprised to discover that the patient, dying in uraemia as a result of what was supposed to be chronic nephritis of one of the usual types, has in reality, at autopsy, a *bilateral pyelonephritis* with shrunken kidneys and an irregularly dilated pelvis. Or, if one has an opportunity to watch many children through adolescence to middle life, he may remember the rare instance of a child with persistent pyelitis who died when a young adult, in uraemia."

This simple and well worded paragraph contains the essentials of a condition which is probably often unrecognized and concerning which sufficiently little has been written to emphasize the difference between chronic nephritis and certain long-standing lesions of the kidneys which are infectious in origin, possibly associated with obstruction. This paper by Longcope and Winkenwerder is one which can be read by the internist and urologist with profit. Only a summary of the essential features is given in this review of their description.

Several writers in the past have drawn attention to chronic pyelonephritis with contracted kidney and have considered that certain of the cases of chronic nephritis were due to an ascending infection of the ureters and renal pelvis. Characteristic features were the presence in the urine of only a moderate amount of albumin with many leucocytes and no casts. In most the blood pressure was elevated, but in some it was normal. Cardiac hypertrophy was sometimes present with a retinitis typical of chronic nephritis. The specific gravity of the urine was low. The majority of the patients were young women. In most cases the disease has ended in death from uremia with small contracted kidneys. The peculiar feature of the disease, as given, was a history of recurring infection of the urinary tract with lumbar pain, in the advanced stages elevated blood pressure, hypertrophy of the heart, elevation of the blood nonprotein nitrogen, and death in uremia, large amounts of urine of low specific gravity which contained small amounts of albumin and leucocytes but *few or no casts* or red blood cells. occasional attacks of fever, with tenderness on palpation of the kidney region and pyelograms that showed narrowing or irregularities of the kidney pelvis with widening of the calyces.

As said the majority of the patients have been young women. Early symptoms, before anuria, are often slight and vague, such as poor health for many years with repeated febrile illnesses, or the continual presence of albumin or pus in the urine. Most of these individuals are not seen, however, until symptoms of renal fail-

ure appear. Headache, nausea and vomiting, anemia, loss of weight, lassitude and dyspnea were the most important symptoms that led them to consult a physician.

Such symptoms drew attention to the urinary findings which were urine in large amounts with a fixed specific gravity at a low level, small amounts of albumin, no casts and many leucocytes, in other words a urine not typical of pure chronic nephritis. Cultures of the urine frequently revealed the presence of the colon bacillus. Cystoscopic examination usually showed a normal bladder with distinctive pyelograms of irregularly deformed kidney pelves, sometimes slightly dilated, with distorted blunted calyces.

Early recognition of this condition, as distinct from the usual chronic nephritis, before the disease has resulted in irreparable destruction of kidney tissue, should be possible through careful examination and scrutiny of available facts. Efforts to assure adequate renal drainage by ureteral dilatation may be of benefit on the theory that there are present narrowings of the ureteral lumen and there is some evidence of this being of some value from the author's experience. Such cases are, perhaps, not rare but are probably seldom dissociated from chronic nephritis.

From a review of 250 cases of *cord bladder* studied at the Mayo Clinic several facts of interest were brought out. The disease affected males much more frequently than females, the ratio being almost 8 to 1. Nearly half of these patients (47.2 per cent) presented themselves for treatment because of urinary tract symptoms, incontinence, chiefly retention and frequency. Such symptoms had often been present for many years so the condition is not necessarily incompatible with a long life. The chief cause of cord bladder in this series of cases was syphilis of the central nervous system (42.4 per cent), and myelodysplasia (developmental defect) of the spinal cord was the next most frequent cause (20.8 per cent). Spina bifida occulta and associated congenital deformities, enuresis in childhood, early onset of symptoms of cord bladder, and loss of other functions of the sacral cord are the characteristic features of myelodysplasia of the spinal cord.

CASE 22051

PRESENTATION OF CASE

A fifty-six year old Italian laborer entered complaining of pain in the midepigastrium on breathing.

For the past two years the patient had been working at night blasting in subways deep under ground, where there was much dust and dampness. About eight months before admission he caught cold and developed a dry cough. Following this he experienced a pain high up in the midepigastrium which was aggravated by deep breathing. It was not affected by food and had no relation to meals. He began to feel below par and had to stop working. He was able to be up and around most of the time but occasionally spent a few days in bed. He had always perspired a great deal. Recently, however, perspiration had become so marked that he wet the sheets of his bed. His cough had remained nonproductive and not very persistent. There were no hemoptyses. Recently his pain decreased in severity but his night sweats became more frequent. He had lost about five or ten pounds during the past eight months. There was no vomiting or blood in the stools. He had some vague joint pains on the right side at the beginning of his illness.

He was first married thirty years ago. His wife died during childbirth. His second wife was living and well. There were three children living and well.

He arrived in this country from Italy thirty-nine years ago. There was no history of typhoid or rheumatic fever. He did not smoke. He drank wine occasionally.

On physical examination the patient was well developed and well nourished and in no apparent distress. He had an occasional dry cough. There were dental caries and pyorrhea. The heart was slightly enlarged. A₂ was loud. There were no murmurs. The blood pressure was 150/88. Examination of the chest showed diminished breath sounds over the right base with a questionable slight increase in fremitus. The abdominal wall was very thick. One examiner believed that he felt the tip of the spleen.

The temperature was 99°, the pulse 95. The respirations were 20.

Examination of the urine was negative. The blood showed a red cell count of 3,800,000 with a hemoglobin of 80 per cent. The white cell count was 3,800, 69 per cent polymorphonuclears. The smear was not remarkable. The stools were negative. A Hinton test was negative. The nonprotein nitrogen was 30 milligrams per 100 cubic centimeters. A phenol-sulphonphthalein test showed 57 per cent excretion in thirty minutes.

An x-ray film of the chest taken in the Out-Patient Department three weeks before admission was reported as follows: "Diaphragm high and in extension on the right. Just above the right diaphragm is a large sharply defined tumor mass. It is homogeneous in density, obliterating the outline of the ribs. In the lateral view it is seen to lie in the anterior part of the chest. The costophrenic angle on this side is shallow. There is slightly thickened axillary pleura. The upper right and entire left lung fields are clear. The heart is in the midline and the measurements are slightly above normal especially in the region of the ventricle."

Further x-ray findings upon admission showed no evidence of organic disease in the esophagus, stomach or duodenum. There was no evidence of a diaphragmatic hernia.

An echinococcus complement fixation and skin tests were negative.

One week after admission a bronchoscopic examination was performed under local anesthesia. The Mosher laryngoscope was passed in order to introduce the 7-10 and 5-15 millimeter scopes in turn for a careful inspection of the bronchial tree in which no pathology was found throughout. The mucosa of the trachea and bronchi was normal throughout and there were no outcroppings, constrictions, secretion, or evidences of displacement of the tracheobronchial tree. Lipiodol was injected into the base of the right lung, with the patient sitting up. The films show that the lipiodol entered the middle lobe bronchi and its divisions and the alveolar structure of the lung as there was no obstruction to the flow of the lipiodol from compression by the mass present. No constrictions or dilations were present in the lower right lobe bronchi posteriorly.

About two weeks after admission he was transferred to the surgical service for exploration of his chest. In preparation he was given an initial pneumothorax, 300 cubic centimeters of air being introduced until the final pressure was minus one to minus three. Four seven and eleven days later he was given 300 cubic centimeters, 500 cubic centimeters, and 600 cubic centimeters of air respectively. Following the last injection x-ray films demonstrated that the mass above the right diaphragm was not within the lung and that it moved with the dia-

phragm The diaphragm was limited in excursion Four weeks after admission the right phrenic nerve was crushed under local anesthesia and three days later an exploratory operation was performed

DIFFERENTIAL DIAGNOSIS

DR JOHN W CASS The history is that of a fatal illness of eight months' duration in a fifty-six year old Italian laborer The predominating symptom is midepigastria pain aggravated by deep breathing and not related to gastrointestinal function Thus, the impression is that the focus for this pain is in the chest

The patient was finally forced to stop his work, the reason for which we are not given but we conclude that it is because of increasing pain After leaving his work he began to have profuse night sweats and perspired easily on exertion There is no mention of chills or fever so that the sweats were probably due to increasing weakness

He had an unproductive cough which was not persistent, and there was no hemoptysis We are led to feel that the pathology causing this cough was not in the parenchyma of the lung necessarily

The pain decreased slightly and the sweating increased, with still no mention of fever Again we interpret this as evidence of a progressive debilitating disease, probably not an infectious process

There was a loss of five or ten pounds of weight in eight months which would be very little weight loss for a gastrointestinal malignancy causing the amount of debility that was present, particularly in view of the statement that there was no vomiting, or blood in the stools With the evidence so far I believe we can rule out gastrointestinal disease at this point

I can attach no significance to the vague joint pains on the right side that were present at the onset of his illness

At physical examination it is stated that he was well developed and nourished and in no apparent distress There was an occasional dry cough but this was evidently not a striking complaint No pathology was noted in the nasopharynx or on examination of the heart In the chest there were dullness and diminished breath sounds at the right base, with a question of an increase in fremitus We now have a positive finding in the chest which leads us to the suspicion that we are dealing primarily with chest pathology It is important that signs of at least complete bronchial obstruction were not found, and also, it is interesting that one observer is stated to have felt the spleen There is no mention of the liver So that we are left with the suspicion of a slightly enlarged spleen and a liver that was normal or decreased in size The

physical examination as given is very sketchy but demonstrates pathology in the base of the right chest

The laboratory findings state that the urine was negative The red blood cell count was 3,000,000 with a hemoglobin of 80 per cent The white cell count was 3,800, with 69 per cent polymorphonuclears and a normal smear This blood report is rather confusing We are looking for a secondary anemia and we have a normal hemoglobin with a low white blood count and a normal smear I should say that the blood picture is not that of pernicious anemia, because of the smear, and that the hemoglobin finding is probably incorrect, and that we really have a secondary anemia The low white blood count is of particular interest and, although one white count is inconclusive, this finding in the absence of a better explanation suggests liver damage, notably a cirrhosis Syphilis I believe can be ruled out by the negative Hinton test The stools are negative, likewise the nonprotein nitrogen and the phenolsulphonephthalein test At this point I believe we can definitely rule out gastrointestinal and kidney disease and narrow the field down to the liver and the right chest

There is no mention of a liver function test which, if done, would be of great help in deciding the question of cirrhosis The complement fixation and skin tests for echinococcus infection were negative and I believe these sufficient to rule out this obscure infection

X-ray examination of the chest locates a large, sharply defined tumor mass just above the right diaphragm, lying in the anterior part of the chest This mass obstructs the outline of the ribs and causes limited excursion of the right diaphragm (I am interested in the statement that the mass is above the diaphragm This finding is difficult to make in a tumor of this location and if the diagnosis which I am leading up to is correct this x-ray finding is incorrect. The remainder of the lung field is clear, with no evidence of fluid or displacement of the mediastinum or evidence of collapse of any of the lung parenchyma This latter finding would be unusual for a tumor within the lung proper

On bronchoscopy it is stated that no pathology was found throughout the bronchial tree and that lipiodol entered the right middle lobe and also the posterior portion of the right lower lobe without demonstrating any pathology No mention is made of the anterior portion of the lower right lobe However, in view of the evidence at hand I feel that if there was any obstruction to the lipiodol in this location it was due to outside pressure Furthermore, the mass is in such a location that it would obscure proper interpretation of lipiodol in the anterior portion of the right lower lobe

The patient was finally given a right pneumothorax and the definite statement is made that the tumor was not within the lung field. The patient was then explored and I am informed that he died shortly afterwards, the cause of death not being a postoperative complication.

Thus, we have a progressive fatal disease of eight months' duration which is not an infection and which is localized in the base of the right chest and is from the evidence at hand and from the history and symptoms not within the parenchyma of the lung. We are left then with a tumor first of the liver, undoubtedly malignant as it killed the patient in eight months and by its size, clinical history and absence of demonstrable focus suggests a primary tumor of the liver. The hint of cirrhosis is a bit more evidence for a primary liver neoplasm; secondly, a tumor of the diaphragm, chest wall or pleura. A leiomyosarcoma of the diaphragm is possible but I would expect, if this tumor was a malignant tumor of the pleura or chest wall that we would have fluid in the chest, considerably more pain than this patient had and evidence of extension into the parenchyma of the lung. My diagnosis is primary cancer of the liver.

PREOPERATIVE DIAGNOSIS

Tumor of the diaphragm

DR. JOHN W. CASS'S DIAGNOSIS

Primary cancer of the liver

PATHOLOGIC DIAGNOSIS

Primary cancer of the liver, hepatoma.

PATHOLOGIC DISCUSSION

DR. TRAUB B. MALLORY: The patient was explored by Dr. Churchill through the thorax under positive intratracheal anesthesia. It became immediately apparent that the tumor lay entirely beneath the diaphragm. The diaphragm was then incised and a large tumor was exposed which evidently arose from the dome of the liver. The liver itself around the tumor was rough and nodular, evidently cirrhotic. The tumor was extremely soft and vascular and ruptured spontaneously when the protective layer of the diaphragm was freed from it. A small piece was taken for biopsy. The hemorrhage was controlled with some difficulty by suturing the diaphragm back to the tumor once more. Dr. Churchill's postoperative diagnosis was primary carcinoma of the liver arising in a cirrhotic liver.

The biopsy specimen showed cells similar to liver cells in appearance, but rapidly growing atypical and evidently neoplastic. Here and

there they surrounded small canaliculi in which were masses of inspissated bile—in other words a typical hepatoma.

I think Dr. Cass's inferential reasoning in reaching his diagnosis deserves a great deal of credit. Primary cancer of the liver in this climate occurs only in individuals with an underlying long standing cirrhosis. In order to make the diagnosis, therefore, one should establish the diagnosis of cirrhosis as well as of malignancy. In this case the most definite evidence was the leukopenia—though in my opinion that indicates splenic congestion rather than hepatic insufficiency. In retrospect two other points can be brought into line. The spleen was apparently felt—a very rare finding in metastatic disease of the liver—and the blood picture was on the whole that of a macrocytic anemia—a characteristic finding in cirrhosis as we have learned in the last few years.

I think it is only fair to point out, and in doing so I do not wish to detract from Dr. Cass's brilliant diagnosis, that this case is an old one and in intervening years we have seen two other cases of primary carcinoma of the liver which elevated the diaphragm in an exactly similar fashion. At the time when Dr. Churchill operated on this patient none of us had seen a case exactly like this. Six days after operation the patient began to pass bloody stools and on several occasions vomited small amounts of bright red blood. This was interpreted as bleeding from esophageal varices secondary to the cirrhosis. He failed rapidly in spite of a transfusion and died eight days after the operation.

CASE 22052

PRESENTATION OF CASE

A fifty year old white single American woman was admitted complaining of histers on her skin.

About three weeks before entry the patient first noticed itchy reddish blotches on her thighs. These resembled mosquito bites. Other than the associated pruritus the patient felt quite well. Shortly afterwards, however these lesions spread up over the buttocks and lumbar region and down the thighs. About one week after the onset several hitches appeared on her wrist and later became raised and hister like in appearance. The histers ruptured spontaneously and discharged slightly milky fluid. The areas were denuded and did not heal although the raw surfaces were dried somewhat by the application of salve. During the succeeding ten days the remainder of the body, the ankles, calves and more prominently, the entire back became involved with histerous lesions. On the abdomen there was only an irregular

blotchy, reddish, maculopapular eruption The lips, mouth, and conjunctival sacs became affected later The mouth seemed to be filled with canker sores, and many blisters appeared within her nostrils For two or three days prior to entry her eyes became bloodshot, sore, and exhibited marked epiphora

An appendectomy for acute appendicitis was done twenty-five years before entry Her menopause occurred four years prior to admission

One year ago there appeared in the left supraclavicular region a mass about the size of an egg which disappeared after x-ray treatment About four months prior to the onset of her current illness she noticed that her abdomen was swelling progressively and that she became somewhat short of breath An operation for ovarian cyst was advised and shortly afterward a laparotomy was performed The surgeon found a large amount of chylous fluid in the peritoneal cavity A small cyst of the left ovary was found but nothing was removed The patient convalesced rapidly Thereafter, however, she began to lose some weight, but the abdomen again became swollen and compensated for the weight loss Six weeks before entry about ten quarts of milky fluid was removed by abdominal paracentesis Some slight swelling of the ankles appeared about this time

Physical examination showed a thin emaciated woman who appeared to be quite ill The skin over the neck, arms, back, legs, and chest exhibited a vesicular, erythematous, desquamative eruption The skin over the back showed peeling of the dermis and several bullae and vesicles Many areas were eroded wet, and oozed serosanguineous material The mucous membranes of the nose and mouth were covered with many shallow ulcers There was slight ectropion with diffuse injection and several small vesicles were observed within the conjunctival sac A few firm, small, discrete nodes were felt in the cervical, axillary and epitrochlear regions The heart was slightly enlarged and a systolic murmur was heard best at the apex The abdomen was full and rounded Both shifting dullness and a fluid wave were elicited The liver and spleen were not felt There was pitting edema of both lower extremities

The temperature was 101°, the pulse 78 The respirations were 20

Examination of the urine showed a specific gravity of 1.020 and a slight trace of albumin The sediment was negative The blood showed a red cell count of 4,500,000, with a hemoglobin of 80 per cent The white cell count was 9,200, 77 per cent polymorphonuclears, 12 lymphocytes, 4 monocytes, 4 eosinophils, and 3 myelocytes

On the second day the patient developed considerable dyspnea Examination elicited the presence of many râles in the right chest On

the following day the dyspnea was more pronounced The respirations rose to 44 The temperature was 102° and the pulse 120 There was flatness over the entire right chest with lessened tactile fremitus, distant tubular breathing and egophony The heart appeared to be displaced to the left, upon which side Giococo's sign was elicited About twenty ounces of yellowish milky fluid was removed by thoracentesis Three days later ten ounces of similar fluid was again removed There was little relief of symptoms She died on the sixth hospital day

DIFFERENTIAL DIAGNOSIS

DR PERRY C BAIRD The bullous eruption in this case probably represents either pemphigus or erythema multiforme The evidence, in my opinion, points fairly conclusively to pemphigus

Both pemphigus and erythema multiforme are diseases which may be superimposed more or less secondarily upon a background of systemic disease of many different types Such a background is usually infectious in nature but may be carcinoma among other things and, on general principles, there is no reason why it could not be Hodgkin's disease as in this case

There is no history of drug ingestion but this should have been inquired into closely in consideration of either diagnosis Arsenic and iodides as well as many other drugs will produce a bullous type of dermatitis medicamentosa closely simulating pemphigus and erythema multiforme

There are several diagnoses which should be mentioned but which are easily excluded—these include bullous leprosy, bullous syphiloderm, bullous impetigo, bullous dermatitis herpetiformis

The onset with itchy reddish blotches resembling mosquito bites suggests an urticarial type of lesion and is in favor of erythema multiforme

The description of irregular, blotchy, reddish maculopapular lesions on the abdomen also suggests erythema multiforme All of these lesions, however, are consistent with what may occasionally be found in association with Hodgkin's disease, which I presume is present in this case

A history of injury or animal bite would have been helpful in diagnosing pemphigus but is not at all essential The absence of this history does not exclude pemphigus

The history and physical examination in all other respects are strongly in favor of pemphigus

The generalized distribution with special mention of buttocks, thighs, wrists, ankles, calves and back is a common distribution in pemphigus

Spontaneous rupture of bullae leaving de-

undated areas failing to heal and a serosanguineous exudate are characteristic of pemphigus.

Involvement of the lips, mouth, nostrils and conjunctival sacs is very common in pemphigus. In a series of cases reported by Pernet and Bullock, all showed involvement of the mouth, nostrils and conjunctival sacs. Erythema multiforme involves these areas rarely or occasionally, much less frequently than pemphigus.

Adenopathy of the cervical axillary and epitrochlear regions should raise, among other things, the question of syphilis. The bullous syphiloderma, however, is seen only in infants with hereditary lues and is confined usually to the palms and soles. The albuminuria and fever present in the case are common findings in pemphigus.

The fatal issue is strongly in favor of pemphigus but may occur rarely in erythema multiforme.

A Pels-Macht test would have been interesting though I do not think that the differential is to be regarded as difficult enough to warrant it.

The diagnosis of either pemphigus or erythema multiforme does not help us in surmising what may have caused the accumulation of a chylous fluid in the peritoneal and right pleural cavities. The history of an egg sized mass in the left supraclavicular region disappearing on x-ray treatment suggests lymphoblastoma and I presume that Hodgkin's disease involving the mediastinal glands could lead to obstruction of the thoracic duct with consequent collection of a chylous fluid in the peritoneal cavities.

One case of chylothorax due to lymphosarcoma reported by Irons showed disappearance of fluid following deep x-ray therapy. The results of such therapy would have been helpful in this case.

Skin lesions with severe itching, pigmentation, ulcers and small granulomata, vitrearia, and erythematous nodules have been described in Hodgkin's disease and suggest a possible linkage in this case between the skin lesions and probable underlying systemic disease. I am unaware, however, that lymphoblastoma of the skin could give rise to a bullous reaction.

My diagnoses are pemphigus and Hodgkin's disease.

DR. MYER M. TOLMAN Every now and then we see a case of pemphigus usually with an onset similar to that which this patient showed, with symptoms of an underlying Hodgkin's or lymphoblastoma. We made that diagnosis in this case. It appears that these manifestations are pemphigoid lesions and not true pemphigus as such. We know that Hodgkin's disease and lymphoblastomas in general can in the end stages cause an eruption not unlike either erythema multiforme or pemphigus of the toxic type. A Pels-Macht test was done but it went

astray. I do not think it would make much difference either way because a toxic eruption such as this case presented would give the same amount of toxicity by the test that pemphigus would. It was our impression that this woman had Hodgkin's disease and died of it, and that the pemphigoid lesions were a manifestation of the disease rather than a true pemphigus in a case of Hodgkin's disease.

CLINICAL DIAGNOSES

Hodgkin's disease
Pemphigus

DR. PERRY C. BAIRD'S DIAGNOSES

Hodgkin's disease
Pemphigus

ANATOMIC DIAGNOSES

Pemphigus.
Lymphoblastoma, sarcomatous type, retroperitoneal, mesenteric and axillary.
Peritonitis acute and chronic, generalized.
Pleuritis, acute fibrinous, right.
Hemohydrothorax left.
Pyothorax, right.
Pulmonary congestion bilateral.
Pulmonary atelectasis, right.
Pleuritis chronic fibrous left apical.
Paralytic lens.
Ovarian cyst left.
Fatty vacuolization of liver.
Leiomyoma, broad ligament, right.
Hydronephrosis, left.
Hydronephrotic, left.
Thyroid cyst, right lower lobe.
Operative scar. Exploratory laparotomy.

PATHOLOGIC DISCUSSION

DR. TRACY B. MALLORY We take up dermatological cases here all too rarely for two reasons. One is that it always seems to me very unfair to ask the dermatologist to try to make a diagnosis from a purely verbal description of the lesion. I find it so utterly impossible myself to describe these lesions in a way that makes one sound at all different from another that it seems to me nearly impossible to put in words differences that would be quite obvious to the eye and palpation. The other reason for not taking up these cases more often than we do is that the pathology department knows nothing about them and few of them have pathognomonic histologic pictures so that we are not able to check the diagnosis and generally take the dermatologist's word for them.

This patient had a lesion that so far as I know is perfectly consistent with pemphigus. I certainly cannot say it was not, and I think Dr. Baird's view that the pemphigus was essentially a terminal manifestation seems entirely reasonable. She did have extensive lymph

phomatous involvement, chiefly limited to the mesenteric and retroperitoneal lymph nodes. It is true there were small glands peripherally but the significantly large ones found at autopsy were all within the peritoneal cavity. The liver and spleen were not involved. The bone marrow was not infiltrated.

Microscopically the nodes show complete obliteration of the architecture and diffuse infiltration by fairly mature lymphocytes, a picture usually termed lymphosarcoma. The final immediate terminal episode was the development of a generalized peritonitis for which a local source was not found, apparently a terminal infection of the ascitic fluid.

DR. BAIRD Did you find the level at which the thoracic duct was obstructed?

DR. MALLORY An effort was made but we could not trace it out.

DR. BAIRD Possibly a very small node in the mediastinum had obstructed it.

DR. MALLORY It is perfectly possible. That is particularly likely here because throughout the nodes there was a great deal of fibrosis, rather peculiar hyalin fibrosis that I have seen two or three times before in lymph nodes undergoing spontaneous contraction in lymphosarcoma.

BACTERIA FREE VACCINE VIRUS

The production of vaccine virus which contains no bacteria has been the dream, for many years, of those concerned with its manufacture. The pulp obtained from the calf always contains some bacteria. Attempts to free the virus of these bacteria and, at the same time maintain the potency of the virus have been unsuccessful. Several procedures have been devised in which the bacteria can be diminished. In fact, the interstate shipment of vaccine virus containing more than fifty bacteria per dose or containing pathogenic bacteria, as determined by animal tests, is prohibited by the U S Public Health Service.

Neguchi¹ was the first to obtain a bacteria free virus which he propagated in the testicles of bulls or rabbits. This gave typical reactions in human beings, but the virus lost its potency rapidly and the method was not practical for propagation on a large scale. The same held true for a neurovaccine, prepared by Levaditi², from the brains of rabbits.

More recent experimentation has shown that the bacteria free testicular virus can be propa-

gated in the living tissue of the chick embryo, either *in vivo* according to the method of Good pasture³ or *in vitro* by the method of Rivers⁴. In the former, the virus-containing material is placed on the chorio-allantoic membrane of an intact embryo, fourteen days old. In the latter, the testicular virus is transferred to tissue cultures composed of minced chick embryo tissue and Tyrode's solution. Multiplication of the virus occurs in each instance and the possibility of adapting one or the other method to the manufacture of virus for large scale Jennerian prophylaxis is apparent.

Results following dermal vaccination with the chick virus grown *in vivo* have been reported by Goodpasture and Buddingh⁵. In a fairly small experimental group the chick vaccine behaved the same as calf vaccine and the immunity conferred, as measured by revaccination and by titrating the antiviral content of the sera before and after vaccination, was identical. In over 1000 field vaccinations with a virus obtained from the 100th generation of the *in vivo* culture, there were 93.6 per cent positive reactions among the primary vaccinations. The potency is reported to be easily maintained and to be uniform. A pustular lesion occurs in the typical positive primary reaction, but the impression was gained that the clinical course was milder. There were no complications or sequelae.

Rivers⁶ has recently reported a very small series of primary vaccinations and revaccinations in which the bacteria free virus prepared *in vitro* has been injected intradermally. The advantages of this procedure are several. The injection is quickly and easily performed and the amount of material injected can be accurately controlled. No open lesion results so that no dressing is required, and the possible danger of secondary infection is avoided. His revaccinations both by intradermal injections following primary vaccinations with calf pulp and by dermal vaccinations with calf pulp following primary intradermal injections, were judged to indicate that the culture virus is an effective immunizing agent, but, they were performed so soon after the primary vaccination that they are not particularly significant. Some difficulty has been experienced in preserving the potency.

It is to be hoped that eventually a bacteria free virus will be available for routine prophylaxis. The work mentioned above is most encouraging, but, none of the vaccinated people have been actually exposed to smallpox and the series is too small to judge the influence of these culture viruses on the incidence of post vaccinal encephalitis. As with other new methods of therapy, which offer improvements over existing successful methods, one should wait until their effectiveness is proved beyond reasonable doubt. This is particularly true of pro-

cedures, such as Jennerian prophylaxis, which are so important from the point of view of public health. One must admit that the mass protection safely conferred by dermal vaccination with the calf pulp manufactured and distributed by the Massachusetts Department of Public Health is as near perfect as is biologically possible!

INDEPENDENCE AND FREEDOM

It is in the American tradition to seek independence and liberty and the mere cry that by any movement in society freedom is threatened, is sure to attract attention and arouse sympathy. Thus, a part of the stock argument of the nonapproved medical schools is that they are the upholders of the American tradition and that they are persecuted for their independent views.

This claim deserves scrutiny. Of what are they independent and for what do they seek freedom? Freedom is not an end in itself. Freedom for action is what is really sought. What is it they desire to do? What are they actually doing?

The independence they seek is independence of all supervision. Control can be exercised formally by some legally constituted authority, or informally by public opinion. Formal control can be avoided under certain conditions. Informal control is inescapable if public opinion is enlightened.

This is realized by these schools and thus every effort is made to cover up and hide what they are doing. Exactly what they are doing outsiders do not know, but a fair general estimate can be made on the basis of what has been found in some schools in the past and the probable reactions of human nature under certain conditions. Since they strive so valiantly to prevent investigation, undoubtedly they have something which it is to their advantage to cover up and to their disadvantage to disclose. One's curiosity is stimulated.

It was reported some months ago that the survey of medical schools in the United States and Canada might include all schools, as osteopathic and nonapproved medical schools were to be invited to participate. It is now reported that certain of the nonapproved schools have refused to pay any attention to the letters of invitation not even acknowledging their receipt.

The history of the investigation of medical education in Massachusetts, proposed during the 1935 session of the General Court is interesting. Opposition was expressed by representatives of the nonapproved schools on the ground that the Commission would be packed against them, that in the nature of the case, the Commission would be prejudiced. It was a gratuitous insult to the duly constituted governmental authorities. The composition of what they would consider an "unprejudiced" commission would be an interesting subject for study. Doubtless they would agree with the old lady who, watching the soldiers march by, observed that they were all out of step except her son John.

Independence and freedom without qualification cannot exist. They must be restricted, in the interest of other individuals, usually in groups manifesting social control. Educational institutions such as medical schools are quasi-public institutions.

The independence and freedom in medical education claimed by nonapproved schools would entitle them to give a medical education satisfactory to themselves. It would not entitle them, as they claim, to forbid the satisfaction of the state and to force upon the state uneducated physicians. In the protection of the public against unqualified practitioners, the state may properly, and as things are now, should insist that all physicians receive a reasonably good medical education before being admitted to examination for license to practice.

In so far as the graduates of medical schools are to be candidates for licensure to practice medicine, to this extent the independence and freedom of all medical schools to do as they please should be restricted, for the protection of the public, if it pleases these schools to degrade medical education.

THE CONQUEST OF PESTILENCE

THE septic appearance of death rate graphs of almost the entire nineteenth century was due to pestilence. By comparison the influenza epidemic of 1918, raising the deaths in New York City from approximately 14.5 per thousand to about 18 per thousand of population looks like a minor flareup of temperature during the defervescence of an acute and stormy infectious illness. The story of the conquest of pestilence is told by Dr. Charles F. Bolduan, director of Health Education in the New York City Department of Health, in *The Milbank Memorial Fund Quarterly* for July, 1935.

In 1798, yellow fever showed 1,500 deaths in a population of approximately 60,000, and in that same epidemic sixteen of the forty practicing physicians fell victims to the disease. Yellow fever reappeared repeatedly, there being 200

cases recorded as late as 1870 Smallpox was present almost constantly, causing 1,666 deaths in 1872 over 500 in 1881, and 132 as late as 1891 The other contagious diseases also played their parts measles being responsible for 443 deaths in 1836-37 and 1,032 in 1891 Scarlet fever accounted for 579 fatalities in 1836-37 and diphtheria for 4,509 in 1887

The real paines, however, were caused by the various epidemics of cholera, following those in Europe, and during them the prevailing death rate was approximately doubled jumping, during one epidemic from 25 to 50 per thousand of population In 1832, with a population of slightly over 200,000 the city experienced 3113 deaths from cholera in 1849, with a population of 515,000, 5,071 deaths, and in 1874 2,009 deaths, smallpox causing 611 in the same year By comparison the influenza in 1918 causing 12,562 deaths in a population of over five and a half million pales into comparative insignificance The average death rate of something over 25 per thousand until 1890, sometimes doubled, has fallen steadily during the last forty odd years to 10.2 per thousand in 1915

As Dr Bolduan states, such a calamity as a doubling of the death rate in the present state of medical knowledge and application is so remote as to be almost unthinkable Other causes of death, however, have been assuming even greater importance Tuberculosis and syphilis both preventable diseases, still rank among the major causes of death Our efforts must be directed toward diseases of the cardio arterio-renal system cancer and diabetes appendicitis and automobile accidents and something must be done to reduce maternal mortality and the deaths of infants during the first month of life

The Committee on State and National Legislation of the Massachusetts Medical Society has voted to

SUPPORT

Senate 321 Resolve—Directing the Department of Public Health to investigate the feasibility, necessity and cost of a new hospital for the treatment of infantile paralysis and arthritis

The title is self explanatory, the results to be reported to the General Court with their recommendations, by June 1, 1936

Petition of Charles T Daly

Given to Public Health Hearing Thursday, February 6, 10 30 A M, Room 450, State House, Boston

House 34 An Act relative to the qualifications of applicants for registration as qualified physicians

Introduced by the Board of Registration in Medicine

This bill prescribes certain higher standards than are now required for applicants as practitioners. New requirements are two years of college and both college and medical school must be approved

FAVOR

House 59 An Act defining stillbirths

This Act amends the present laws with an exact definition of stillbirths

Introduced by the Secretary of the Commonwealth.

Given to Public Health Hearing Thursday, February 6, 10 30 A M, Room 450, State House, Boston

TO OPPOSE THE FOLLOWING BILLS

Senate 20 An Act providing for the construction and maintenance of a hospital for the care and treatment of victims of infantile paralysis

This authorizes the state to build and maintain a hospital specializing in the treatment of infantile paralysis in the metropolitan district

Introduced by Senator Madden

Given to Public Health Hearing Thursday, February 6, 10 30 A M, Room 450, State House, Boston

Senate 24 Bill abolishing the several boards of trustees of certain state institutions and transferring their functions to the Governor and Council

This gives to the Governor and Council all the powers formerly given to the boards of all institutions in the Department of Mental Diseases and Public Welfare

Introduced by Senator Joseph A Langone, Jr

Senate 51 Bill establishing and maintaining at North Reading State Sanatorium a division for the care and treatment of persons suffering from cancer

This simply authorizes the establishment at North Reading of a cancer hospital, as is now being conducted at Pondville

Petition of Senator Charles T Daly

Given to Public Health Hearing Thursday, February 6, 10 30 A M, Room 450, State House, Boston

Senate 322. An Act to provide for the construction and maintenance of a health center for the care and treatment of persons suffering from infantile paralysis

This bill authorizes the establishment of a health center for infantile paralysis, preferably on Buzzards Bay. The center shall be equipped for treatment, recreation, etc, and shall help out those needing financial aid

Petition of Senator Frank Hurley

Referred to Public Health Hearing Thursday February 6, 10 30 A M, Room 450, State House, Boston

Senate 323 An Act relative to the practice of optometry

This Act amends the present law and defines who may practice optometry in this state. It makes physicians and surgeons subject to the rules of the Board of Optometry. It also states the methods by which, and the reasons for which, a person can have his license revoked

Introduced by Massachusetts Society of Optometrists

Senate 388 An Act providing for representation on the Board of Registration in Medicine of the several medical schools of the Commonwealth authorized to grant the degree of doctor of medicine

This provides that of the seven members of the Board of Registration there shall be one representing Harvard Medical School, one Boston University School of Medicine, one Tufts College Medical

School one Middlesex College of Medicine and Surgery one College of Physicians and Surgeons of Boston, one Massachusetts College of Osteopathy and the seventh not designated.

Introduced by Paul J. Campbell.

Given to State Administration. Hearing Monday March 2 10 00 A.M., Room 423 State House Boston

House 574 An Act to require hospitals receiving public support to accord equal rights of admission to patients of all duly registered physicians

It states moreover that all the hospital facilities shall be open to every registered physician.

Introduced by Charles F. Wokeling.

Given to Public Health. Hearing Thursday February 6 10 30 A.M. Room 450 State House Boston

House 662. Bill providing for the regulation of the practice of physicians and surgeons in certain cases

This provides that no physician may remove a patient's limb or organ without the consent of said patient (if sane) or of patient's nearest relative. Any organ removed to be saved to show whether said operation was necessary.

Petition of Annie D. Brown.

Referred to Public Health. Hearing Thursday February 6 10 30 A.M. Room 450 State House Boston

House 949 An Act to defend our inalienable Constitutional rights to the freedom and security of our person against compulsory vaccination or inoculation.

This provides that nobody need be vaccinated without his consent or in the case of minors without the written consent of their guardians. Vaccination shall not be made a requisite for admission to public schools.

Petition by Citizens Committee Opposing Compulsory Vaccination.

Referred to Public Health.

House 1444 An Act relative to the establishment of a board of examination and registration to regulate the practice of chiropractic.

Introduced by James E. Ward.

Referred to Public Health.

House 1458. A petition for legislation to create a board of examination and registration to regulate the practice of magnetic healers.

Introduced by Arsene Pare.

Referred to State Administration. Hearing Monday March 3 10 00 A.M., Room 423 State House Boston

NO DECISION (REFERRED TO COUNCIL)

House 35 An Act for the annual registration of physicians and the publication of a list of registered physicians

This bill provides that for an annual fee of two dollars, the physicians shall be registered annually and said list shall be published. This bill is designed to eliminate unlicensed practitioners

Introduced by Board of Registration in Medicine Given to Public Health. Hearing Thursday February 6 10 30 A.M. Room 450 State House Boston

MISCELLANY

SPECIFIC TREATMENT FOR LOBAR PNEUMONIA

Lobar pneumonia is the seventh leading cause of death in Massachusetts. Type I or Type II pneumococci are the cause of the disease in over one-half of the cases.

The case fatality rate of Type I pneumococcus pneumonia untreated with serum is approximately 75 per cent out of Type II 41 per cent. The expected death rate in these two types can be much reduced by early specific treatment. Of 504 Type I cases in the Massachusetts Pneumonia Study which were treated with serum within the first four days of the illness only 56 or 11.1 per cent died. Of 136 Type II cases similarly treated 37 or 27.2 per cent died. This experience in Massachusetts has demonstrated that specific treatment can be successfully used by physicians in general practice.

Success in specific treatment depends for the most part upon the early use of serum. Thus the type of pneumococcus infection should be determined at the earliest possible moment. The importance of the time element is emphasized by the experience in Massachusetts. Of 377 Type I cases treated during the first three days 32 died (8.5 per cent) and of 137 treated on the fourth day 24 died (18.9 per cent).

DETERMINATION OF TYPE OF PNEUMOCOCCUS INFECTION

The type of infection is more readily determined by examination of the sputum than by other means. The specimen should come from the lung with as little admixture of saliva as possible. It is desirable to obtain at least a teaspoonful of sputum, which is collected in a clean wide-mouthed bottle or cardboard sputum box, and to send it at once, preferably by messenger to the nearest laboratory equipped for typing. Special containers are available through local Boards of Health. *No antiseptic* should be added to the sputum. Tuberculosis sputum contents should not be used as they contain carbofolic acid.

The Neufeld method of typing is rapid, simple and reliable and has supplanted other methods. It is applicable to pneumococci from any source and usually permits identification of type within a few minutes.

Typing will be done without charge at the State Bacteriological Laboratory, Room 527 State House, Boston. In case of emergency typing of sputum from patients for whom serum therapy is applicable will be done during the night week-ends, or on holidays. Such specimens should be left with the State House Guard. All sputums showing Type I or Type II pneumococci are reported by telephone or telegraph prepaid.

In addition to the State House Laboratory typing facilities are also available elsewhere. The charges

for the typing depend on the laboratory Typing in Boston is done at the following hospitals Boston City, Faulkner, Evans Department of the Massachusetts Memorial, and the New England Deaconess

Elsewhere in the State facilities have been established for pneumococcus typing in 57 laboratories, i e

SPECIFIC SERUM FOR TREATMENT

Specific serum for the treatment of Type I or II pneumococcus pneumonia is available to physicians through the State Laboratory, Room 527, State House, Boston, or through the laboratories of any of the hospitals listed above, provided that

- (1) Sputum or other material from the patient is first typed and found to contain Type I or II pneumococci
- (2) The physician certifies that the patient has not been ill longer than four days (96 hours)
- (3) As soon as the patient is discharged, the physician agrees to make a report to the Massachusetts Department of Public Health on a form enclosed with the serum

Under these conditions 60,000 units of concentrated serum (Felton's antibody solution) will be issued for each Type I pneumonia and 100,000 units for each Type II case

Bacteremia occurs in about one-quarter of the cases with Type I and one third of those with Type II pneumococcus pneumonia and is a very serious condition This information in relation to bacteremia is of great importance in treatment It is desirable to make a blood culture in each case before the first dose of serum is given If the first blood culture is positive, or, if negative, and the progress of the case is unsatisfactory, it is desirable to continue to take blood cultures at intervals of about twenty four hours Blood cultures may be sent for examination to the State Bacteriological Laboratory

Experience has shown that some cases require more serum than others An additional 60,000 units of serum may be obtained from any of the above mentioned laboratories if any of the following conditions are present

- (1) The patient has a bacteremia as shown by finding Type I or II pneumococci in cultures of his blood
- (2) The patient is pregnant or has been delivered within seven days of the onset of pneumonia
- (3) If the temperature does not drop below 101° F by mouth within 18 hours of beginning serum treatment, or, if having dropped, it again rises above this level within 48 hours

Further information concerning the administration of serum will be found in the circular accompanying the serum The directions given in the circular should be followed in detail

NURSING SERVICE FOR PNEUMONIA

Clinical experience has shown that patients receiving prompt medical and nursing care have the best chances of recovery In almost every part of

the State nursing service on a visit basis is available through the visiting nursing associations for patients not needing or who cannot afford a special nurse. In Boston the Community Health Association will give nursing care on a visit basis on the order of a physician. This Association will be glad to cooperate with physicians by sending a specimen of sputum for typing.

PNEUMONIA COMMITTEE, BOSTON HEALTH LEAGUE

DR. FREDERICK T. LORD *Chairman*,

MISS FLORENCE M. PATTERSON

MISS MARGARET H. TRACY *Secretary*

CHANGES IN THE STAFF OF THE MILTON HOSPITAL

Dr. Carlston A. Rowe of East Milton has been appointed chief of the staff of the Milton Hospital to succeed Dr. M. Vassar Pierce who has held this position since the hospital started. Dr. Pierce will be chief medical consultant. Dr. Rowe is a graduate of Tufts College Medical School. Dr. Arthur H. Davison will serve as secretary of the staff and Dr. Walter C. Kite will succeed Dr. Pierce as a member of the executive committee of the staff.

APPOINTMENT OF DR. W. B. KEELER AS HEALTH COMMISSIONER OF BOSTON

His Honor Mayor Mansfield has appointed Dr. William Basil Keeler to the position of Health Commissioner of Boston to fill the vacancy caused by the death of Dr. Mahoney.

Dr. Keeler graduated from Tufts College Medical School in 1903 after a preliminary education acquired in the English High School of Boston, and has served under Dr. Mahoney as assistant to Dr. Charles F. Willensky, Deputy Commissioner of Health, with the assignment as medical inspector for the South Boston Health Unit, one of the groups created under the White Fund.

The position carries with it great opportunities for service and Dr. Keeler may be sure of the cordial cooperation of the medical profession.

APPOINTMENTS UNDER THE SOCIAL SECURITIES ACT

Six Massachusetts physicians will act on the general advisory committee on maternal and child welfare service. Kenneth D. Blackfan, M.D., professor of pediatrics, Harvard University Medical School; Robert B. Osgood, M.D., emeritus professor of orthopedic surgery, Harvard University Medical School; Douglas A. Thom, M.D., director division of mental hygiene, State Department of Mental Diseases; Boston; Robert L. DeNormandie, M.D., instructor in obstetrics, Harvard University Medical School; Bronson Crothers, M.D., Harvard University Medical School; and T. Duckett Jones, M.D., research

director, House of Good Samaritan and instructor in medicine, Harvard.

APPOINTMENT OF DR. LOUIS C. KRESS

Dr. Louis C. Kress, director of the New York State Division of Cancer Control, has been appointed chairman of the state cancer committee of the American Society for the Control of Cancer, succeeding Dr. Barton T. Simpson.—*Science*

RESIGNATION OF DR. WILLIAM HALLOCK PARK

Dr. William Hallock Park retired on his seventy-second birthday anniversary on December 30 from active work as director of the Bureau of Laboratories of the New York Department of Health. He will take a six months vacation after which he will retire permanently as director and become director emeritus. He has held the post for forty-one years. The new William H. Park Research Laboratories named in his honor will have been completed so that they can be dedicated while Dr. Park is still nominally in the city's service. He expects to continue to work at the laboratories in an advisory capacity. Dr. Ralph Mackenness, acting associate director, will be in charge during his absence. Next summer Dr. Park will retire from the Hermann M. Biggs professorship of preventive medicine at the New York University College of Medicine.—*Science*

CORRESPONDENCE

AN EXPLANATION

Editor *New England Journal of Medicine*

Will you kindly publish in the next issue of *The Journal* this letter in order to clarify certain misunderstandings in regard to the column devoted to Obstetrics and Gynecology.

Each week there appears in *The Journal* an article on Obstetrics or Gynecology and while those are under the direction of the Section of Gynecology and Obstetrics of the Massachusetts Medical Society the articles are written by various men and not, as seems to be the general impression written by the Officers of the Section. Some of the articles published have brought forth comments but in order that no misunderstanding may exist we wish it understood that both the title and subject matter of any paper published represent the individual viewpoint and responsibility of the writer of that article.

In the issue of *The Journal* for January 16, 1936 there appears an article on "Interruption of Pregnancy" which is a highly controversial subject and the views therein expressed have caused considerable comment.

As Chairman of the Section I wish to state without qualification, that the Section does not advocate or endorse the use of abortion as a therapeutic measure. The statements made in the article referred to are the opinions of the writer of the article from his experience and according to his judgment.

May I also say, in order that my personal opinion may be on record, that I do not now and never have believed in the termination of pregnancy before the age of viability

CHARLES J. KICKHAM, M.D., *Chairman*,
Section of Gynecology and Obstetrics,
Massachusetts Medical Society

PHYSICIANS' GROUP IN THE COMMUNITY FUND CAMPAIGN

January 24, 1936

Editor, *New England Journal of Medicine*,

Due to certain inaccuracies appearing in the January 16 number of *The New England Journal of Medicine* regarding the personnel of the Physicians' Group in the Community Fund Campaign I give below a correct list of the organization of this group

Vice Chairmen Dr James A. Halsted, Dr George C. Shattuck

Lieutenants Dr Theodore Badger, Dr Myles Baker, Dr Laurence Ellis, Dr Henry Faxon, Dr Trygve Gundersen, Dr Charles C. Lund, Dr Francis Rackemann, Dr William M. Shedden, Dr Richard Stetson, Dr Augustus Thorndike, Jr., and as solicitors some seventy other doctors

JOHN P. MONKS, M.D., *Group Chairman*

TYPING SERVICE AT THE FAULKNER HOSPITAL

January 21, 1936

Editor, *New England Journal of Medicine*,

In your issue of January 16 on page 131 under correspondence, there is a letter by the Commissioner of Public Health of the Commonwealth in regard to the abuse of diagnostic service. In the first paragraph he calls attention to the fact that the Department of Public Health through its diagnostic laboratory offers an opportunity for typing of sputum at any hour of the day and adds that in this respect it is offering a service that is not available even in the hospitals of the State. I do not know about other hospitals in the State, but I would like to call attention to the fact that The Faulkner Hospital, which is a community hospital for the patients of physicians who are on the Executive or Associate Staff, offers service for typing sputum from pneumonia patients throughout the twenty-four hours of the day

C. FROTHINGHAM, M.D.

Jamaica Plain, Mass

UNITED STATES DEPARTMENT OF AGRICULTURE

Extension Service

January 17, 1936

Medical Society of the State of Massachusetts,

We are now arranging our annual conference for Extension Service workers in the twelve Eastern

States which will be held in Boston, at the Hotel Statler, February 19, 20 and 21, 1936. The extension specialists in Clothing will be one of the groups attending this conference

You are doubtless familiar with the broad scope of the Home Economics Extension Program carried on with rural women. The clothing work which is one phase of the homemaking program aims to help farm families dress suitably, becomingly and economically. Through this Service, farm women and girls learn to make and remodel garments as well as study selection of materials and ready-made clothes. In connection with this project, our extension workers are constantly asked for information and advice on the following matters:

- 1 Selection and fitting of shoes
- 2 Types of foundation garments
- 3 Scientific care of complexion and hair

At the February Conference, it is our desire to bring our specialists some help along these lines and we wish to ask for your suggestions as to available speakers who would present these matters from a scientific angle. We will appreciate it if you will refer us to physicians or other qualified speakers who could appear on our program.

Some members of your association may have written articles on these topics. If so, we would be glad to have the references.

FLORENCE L. HALL,

Extension Home Economist

Washington, D. C.

THE CAMPAIGN AGAINST PNEUMONIA

The Commonwealth of Massachusetts
Department of Public Health
State House, Boston

January 24, 1936

Editor, *New England Journal of Medicine*,

Thank you for your interesting letters of the twenty-first. You ask if we can send you material on the work done in Massachusetts on pneumonia. Let me say that we are in the process now of drawing up the final report of that work. This should be available within a couple of weeks. I doubt very much whether any considerable part of the report will ever be published, but there are some things which I think it would be very wise to get into the literature, but we would have to decide that later when we have all our facts and figures together.

It is very gratifying to have you interested in this pneumonia work. You ask if in our opinion the figures you sent in one of your letters were approximately correct. This is difficult to answer in an off-hand manner because an examination of those figures shows clearly that the estimation of the number of lives that may be saved by the early use of serum depends largely on what death rate a person is willing to accept as the usual death rate in serum-treated cases. I have recomputed these figures, as you will see below, and my totals are somewhat different from the ones given in your letter. I do not know on what your figures are based, but my com-

putation is based on a careful review of the literature to determine the usual death rate of Type I and II cases not given serum and the death rate of cases of those two types treated during the past five years in this State with serum. The death rate in Type I cases without serum is 25 per cent, and in our series with serum in the first four days of illness is 11 per cent. Thus the use of serum allowed a reduction in the usual death rate of about 56 per cent. In Type II cases without serum the death rate is 41 per cent and in our series with serum is 27 per cent allowing a reduction of 34 per cent in the death rate.

You state your figures are based on the U S Public Health Reports for 1934. I do not have those at hand, but I have some that I did some time ago. These are tabulations of the death statistics from the U S Registration Area for the ten years of 1920-1929 inclusive. There were 1,000,889 deaths from pneumonia of all forms in the area in that period. Of these, 583,759 were caused by lobar and undefined pneumonia, and 423,110 by bronchopneumonia and capillary bronchitis. For ordinary purposes of computation the first group is considered simply as lobar pneumonia and the second group simply as bronchopneumonia. Estimating the usual death rate of lobar pneumonia at 25 per cent, there were four cases for each death. This would give anually 237,504 cases of lobar pneumonia. We have done the same thing for bronchopneumonia and estimated that there are 163,244 cases yearly. This latter figure may be too high, however because nobody really knows what the usual death rate in bronchopneumonia is likely to be. In any event, to proceed, we have found in a collected series of typed lobar pneumonia cases in the literature that in over 3,000 cases pneumococci caused about 95 per cent of the cases. If we apply this 95 per cent figure to the total number of lobar pneumonia cases estimated to occur in this country each year we find that there were 225,838 cases of pneumococcus lobar pneumonia yearly in bronchopneumonia, however only about half the cases are due to pneumococci thus there would be 84,023 broncho cases each year.

The totals of these figures then would show that there are in the United States each year approximately 310,250 cases of pneumococcus pneumonia.

In a series of nearly 10,000 typed cases of lobar pneumonia we have collected from the literature Type I was responsible for 88.4 per cent, and Type II for 23.3 per cent of the cases. If these percentages are applied to the total pneumococcus lobar pneumonia cases estimated to occur here each year we find that there are 127,933 cases of Type I or II pneumococcus lobar pneumonia annually. In bronchopneumonia our figures for type incidence rest on much less secure ground and are based on around 400 cases which have been typed. This series showed that Type I caused 2 per cent and Type II, 3 per cent of the cases. Applying these percentages to the pneumococcus bronchopneumonia cases,

we find that these together total about 4,231 cases annually.

The totals for the Type I and II pneumococcus pneumonia cases both lobar and broncho show that there are annually about 182,162 cases occurring in this country.

To condense all this and make it comparable to the figures you sent me let me say that each year in the United States there are 310,250 cases of pneumococcus pneumonia, of which 182,162 are Types I or II.

Type	No. Cases	Probable Deaths Without Serum	Probable Deaths With Serum	Lives Savable
I	77,052	19,368	8,476	10,787
II	55,110	22,595	14,880	7,715
Totals	132,162	41,963	23,356	18,502

I think these figures are as accurate as can be computed at the present time. It should be appreciated, however, that they represent estimates and nothing more. I hope this information will be of some value to you.

ROBERTICK HEFFRON M.D.

RECENT DEATHS

ROBERTSON—JAMES DOUGLAS ROBERTSON, M.D., of 1 Anburn Court, Brookline, Massachusetts, died at his home January 25 1936. He was born in Perth Scotland in 1883 and graduated from the College of Physicians and Surgeons, Boston, in 1894.

He was active in the Masonic order and several fraternal societies.

PACKARD—HORACE PACKARD, M.D. a retired surgeon of Stoughton and 470 Commonwealth Avenue, Boston died January 24 1936, in Stoughton, Massachusetts. Dr Packard was born at Bridgewater Massachusetts in 1855 and graduated from the Boston University School of Medicine in 1880. He subsequently studied in Berlin, Prague, Paris, London and Vienna.

He was consulting surgeon at the Massachusetts Homeopathic, the Newton and Brockton Hospitals. He was for many years professor of surgery at the Boston University School of Medicine.

Dr Packard joined the Massachusetts Medical Society in 1907 and retired in 1925. He was a member of the American Institute of Homeopathy, the American Medical Association, the Massachusetts Homeopathic Medical Society and the Massachusetts Surgical and Gynecological Society. He was also a member of the Boston City Club, the Twentieth Century Club and the University Club.

CLARK—**WILLIAM L CLARK, M D**, of Philadelphia, well known throughout the country as a pioneer in the use of electricity in surgery, died January 12, 1936

He visited Boston on several occasions to address various medical groups and made many friends in this locality. Prior to June 1935, he was for three years President of the Academy of Physical Medicine. He was an Honorary Fellow of the New England Physical Therapy Society, a Fellow of the American Medical Association, American College of Radiology, American Radium Society, and was actively identified with several other medical and surgical groups.

His widow, Mrs. Mary Clark, four sons and two daughters survive him. A sister, Mrs. Sydney Cornell, resides in Newton.

NOTICES

ANNOUNCEMENT REGARDING APPOINTMENT OF SENIOR MEDICAL INTERNES BY THE UNITED STATES PUBLIC HEALTH SERVICE

The United States Public Health Service will consider applications to fill a number of vacancies which exist at the present time and also vacancies which will occur about July first next, for second-year medical internes. Any young physicians, not over thirty years of age, who have graduated from a Class 'A' medical college and who have completed, or will shortly complete, one year's internship in an approved hospital are eligible to apply.

The Public Health Service desires to secure applications only from candidates who are interested in the Service as a career and who desire to request permission to appear before a board of commissioned officers for examination for appointment as Assistant Surgeons in the regular commissioned corps, on or about the time they will complete a year's service as internes in the Public Health Service.

Those interested in making application should address an inquiry to the Surgeon General, U S Public Health Service, Washington, D C, stating the date they will be available for duty and more complete information and the necessary blanks upon which to make application will be furnished.

POSTGRADUATE INSTITUTE IN PHILADELPHIA*

A Postgraduate Institute, offering an intensive and interesting study of the newer work in the field of cardiovascular and renal diseases, will be conducted by the Philadelphia County Medical Society during the week of April 20 to 24, inclusive.

The program, to be held in the Bellevue-Stratford Hotel, Philadelphia, has been designed to meet the needs of all members of the profession, but particularly those in general practice. Physicians from all parts of the eastern and east central United States are invited to attend.

Lecturers, about thirty in number, have been selected from among the foremost teachers in this

great center of medical education. The medical faculties of the University of Pennsylvania, Jefferson, Temple, and the Woman's Medical College of Pennsylvania are represented on the program. While approaching the subject from specialized viewpoints—those of the physiologist, cardiologist, pediatrician, surgeon, roentgenologist, bacteriologist, internist—the presentations will be of a strictly practical nature, and should be of real value to the general physician, who finds cardiorenal conditions occupying a large proportion of his time.

The Philadelphia County Medical Society, in conducting the Postgraduate Institute, is meeting the demands of many physicians, who have felt that the organized profession should provide them with this type of opportunity for keeping abreast of medical progress and thus maintain the highest standards of medical service. The only charge is a \$5.00 registration fee to cover the Institute's expenses. It is hoped to make the event an annual one, giving special attention each year to a different subject.

MEDICAL CLINIC AND STAFF ROUNDS AT THE PETER BENT BRIGHAM HOSPITAL

At 3:30 P.M. on Thursday, February 6, in the Amphitheatre of the Peter Bent Brigham Hospital, Dr. E. Stanley Emery, Jr., will give a medical clinic. To it are cordially invited practitioners and medical students.

On Saturdays in the wards of the Peter Bent Brigham Hospital, from 10 to 12, staff rounds will be conducted by Dr. Christian.

A CORRECTION

The Baker Memorial Clinic of the New England Deaconess Hospital was referred to in a footnote appearing on page 45 of our issue of January 9. It has been brought to our attention that the footnote should have read "From the Lahey Clinic, the George F. Baker Clinic of the New England Deaconess Hospital and the New England Baptist Hospital."

FUNCTIONAL ASPECTS OF BASES OF BEHAVIOR

This is a course which gives wide information and important insight into phases of education both outside and inside the school's educational program. It makes such practical application of certain principles of mental hygiene that it offers direct and specific suggestion to those who would put these principles into practice. For information as to the names of lecturers apply to Boston University School of Education, 29 Exeter Street, Boston.

BOSTON DISPENSARY

25 Bennet Street, Boston

MEDICAL CONFERENCE PROGRAM

9-10 A.M., February, 1936

Saturday, February 1—Presentation of Ward Case.
Dr. P. A. F. Hoefler

Tuesday, February 4—Shoulder Conditions. Dr. John D. Adams

*See Advertising Section, page ix.

Wednesday February 5—"Indications for Various Methods for the Relief of Prostatic Obstruction." Dr Harold A. Chamberlin.

Thursday February 6—Endocrine Clinic. Dr Charles Lawrence.

Friday February 7—Objective Studies in Angina Pectoris. Dr Joseph Riseman.

Saturday February 8—Presentation of Ward Case. Dr Jacob Schloss.

Tuesday February 11—Recognition of the Early Psychoses Their Differentiation from Neuroses Dr A. Warren Stearns.

Wednesday February 12—"Mistakes Made in the Diagnosis and Treatment of Syphilis."—Dr Francis Thurmon.

Thursday February 13—Social Service Case Presentation. Miss Edith Canterbury

Friday February 14—"Pituitarytropic Studies." Dr Saul Hertz.

Saturday February 15—Presentation of Ward Case. Dr H. C. Gordinier

Tuesday February 18—X Ray Demonstration. Dr Alice Ettinger

Wednesday February 19—Auscultation of the Abdomen Dr Nell Stevens.

Thursday February 20—Heart Clinic. Dr Samuel H. Proger

Friday February 21—"Some Aspects of Clinical Endocrinology" (With Motion Pictures.) Dr Lewis M. Hurxthal.

Saturday February 22—Holiday

Tuesday February 25—Case Presentation. Dr Francis McDonald.

Wednesday February 26—"The Present Role of the General Surgeon in a Modern Hospital." Dr Hilbert F. Day

Thursday February 27—Diabetic Clinic. Dr Jacob Schloss.

Friday February 28—Physiological Adventures Abroad. Dr G. Philip Grabfield.

Saturday February 29—Presentation of Ward Case. Dr H. Magendanz.

NOTICES OF MEETINGS

HARVARD MEDICAL SOCIETY

The next meeting of the Harvard Medical Society will be held in the Peter Bent Brigham Hospital Amphitheatre (Shattuck Street Entrance) Tuesday evening February 11 at 8:15 P.M.

PROGRAM

Presentation of Cases.

The Effect of Hypophysectomy and Adrenalectomy upon Experimental Diabetes in the Cat. By Dr C. N. H. Long University of Pennsylvania, Philadelphia, Pennsylvania.

Medical students and physicians are cordially invited to attend

MARSHALL N. FULTON, M.D. Secretary

GREATER BOSTON MEDICAL SOCIETY

The next meeting of the Greater Boston Medical Society will be held on Tuesday February 4, at 8:00 P.M. in the Auditorium of the Beth Israel Hospital, Boston.

PROGRAM

Speaker Richard Lewisohn, M.D. Visiting Surgeon, Mt. Sinai Hospital, New York City

Subject Recent Advances in the Surgical Treatment of Chronic Duodenal Ulcer

Discussion by Frank H. Lahey, M.D., Arthur W. Allen, M.D., and Charles G. Mixer, M.D.

H. LIXENTHAL, M.D., President

D. B. STEARNS, M.D. Secretary

GREATER BOSTON BIKUR CHOLIM HOSPITAL

The Greater Boston Bikur Cholim Hospital medical meeting will be held Wednesday evening February 5 at 8:30 o'clock at the Nurses Home 45 Townsend Street, Roxbury. Speaker Dr. Abraham Myerson. Subject Neuroses. The profession is invited.

HENRY BAKER, M.D., Secretary

FAULKNER HOSPITAL CLINICAL MEETING

The next clinical meeting will be held at The Faulkner Hospital on Thursday February 6, 1936 at 5:00 P.M. In addition to the usual clinical pathological conference Dr. Harry C. Solomon will talk on "The Application of Fever Therapy in Several Diseases Conditions"

All physicians are invited

NEW ENGLAND HEART ASSOCIATION

The next meeting of the New England Heart Association will be held at the Beth Israel Hospital Boston, Mass., Monday February 8, 1936 at 8:15 P.M.

PROGRAM

1. A Case of Coronary Occlusion with Interesting Features. Dr. Harry B. Levine.

2. Evaluation of Medicinal Treatment of Angina Pectoris. Dr. Joseph E. F. Riseman.

Studies on the Effect of Nitroglycerin on Angina Pectoris. Dr. Morton G. Brown.

3. Incidence of Coronary Heart Disease and Hypertensive Heart Disease in Different Population Groups. Dr. Louis Silver.

4. The Cardiac Output in Patients with Congestive Failure after Total Thyroidectomy. Dr. Mark D. Altschule.

5. A Clinical and Pathologic Study of Aortic Stenosis. Dr. Louis Wolff and Dr. Monroe Schlesinger.

6. A Summary of Clinical Experience in the Treatment of Chronic Heart Disease by Total Thyroidectomy. Dr. Herman L. Blumgart.

All members of the New England Heart Association and interested physicians are invited to attend.

JAMES M. FAULKNER, M.D., Secretary

tirely adequate. The liver was large and firm and some areas seemed to be definitely increased in hardness. Both hepatic and common ducts were tiny fibrous tubes which were impossible to probe. The process seemed to be uniform throughout the entire course of the ducts without stone and without stricture. In the absence of the gallbladder a cholecystenterostomy was out of the question and without any patent hepatic ducts, it seemed likewise impossible to do a hepaticoduodenostomy. A cigarette drain was inserted and the abdominal wall closed. The patient died four days after operation.

A postmortem examination revealed an extensive peritonitis with some intraperitoneal hemorrhage, chronic cholangitis, chronic obstructive jaundice, and chronic infection of the common and hepatic ducts. There was also some fat necrosis from an acute pancreatitis.

These two cases are typical of the pathology to which I wish to call your attention, but not all the patients with this disease have come to such a sad and sudden ending. The inflammatory process, at least in some instances, subsides and the ducts resume their functions.

For instance, Whipple reported a woman of fifty who had been jaundiced for two months. At operation, the gallbladder was found to be collapsed. The common duct and the hepatic duct were felt as a small thickened cord throughout their entire length. Because no dilated duct could be found above, no attempt was made to drain either the gallbladder or the duct system. A biopsy of the liver showed biliary cirrhosis. Nine days after operation, the patient began to show some bile in her stools and continued to recovery. As far as was known she has remained well.

In regard to the ideal treatment of this condition, if the gallbladder is present, probably the best procedure is a cholecystostomy or a cholecystenterostomy to facilitate drainage of the biliary system with the hope that the inflammation will subside and the constriction will be relieved.

If the gallbladder has been removed, then a hepaticoduodenostomy should be done over a rubber tube provided that one can find a patent hepatic duct or either of its branches. A number of cases have been cured by this procedure. In one of Judd's patients the tube remained in situ for five years and was removed through the duodenum at a secondary operation because of a return of symptoms due to an encrusting obstruction of the tube with bile salts.

Prognosis should always be guarded because of the well-known tendency to stricture formation with any form of a reconstructed duct and the definite possibility of a continuing infection with increasing biliary cirrhosis and destruction of hepatic tissue. However, one should not rush toward re-operation at the first sign of returning difficulty, for some of these patients have cleared up after a considerable period of trouble including pain, chills, and intervals of jaundice. On the other hand second-

ary operations are not entirely hopeless because a few have been relieved after several attempts and have remained well over a period of years.

My immediate personal interest in the subject was aroused on account of a case with which I struggled for the greater part of last year and I would like to report her story at this time.

A young married woman of thirty-three was admitted to the Baker Memorial on May 8, 1934 for study. Her story was that she had been perfectly well until one year before admission when she had a slight attack of upper abdominal discomfort which lasted for several minutes. During the past year, she had had six or seven similar attacks. Two weeks ago the upper abdominal pain and discomfort became more or less constant. It was not very severe and did not radiate to the back. Eight days ago her family physician put her on a milk diet with only slight relief. The most important item as a result of our studies was the x-ray examination which showed a gallbladder filled with stones. A cholecystectomy was done on May 18, 1934 under spinal anesthesia. There was a good exposure and the gallbladder was easily removed by dissecting from the cystic duct upward. She made a satisfactory postoperative convalescence and was discharged fifteen days later. The small sinus was still draining a little bile.

This sinus closed and five weeks after her discharge from the hospital she began to be jaundiced, there was no pain but she did have loss of appetite and loss of weight and strength. She was readmitted with a diagnosis of obstructive jaundice and question of stone in the common duct.

An exploration was done on July 6, 1934. At this time the liver was very small, dark colored, and had a rather rough surface. The common duct was exposed after freeing up the adhesions underneath the lower edge of the liver. The common duct was found to be a small, hard, cordlike structure throughout its entire length. An opening was made in the anterior wall of the duodenum and an attempt was made to probe the common duct from below. This was unsuccessful as the probe could not be introduced into the common duct. The duct was then cut. Apparently there was no lumen or at least only a very tiny one, not large enough to admit a fine probe. This duct was followed up to the liver and still no lumen could be demonstrated. The patient was beginning to show the strain of operation, a cigarette wick was placed underneath the edge of the liver and the wound closed.

The patient was in poor condition and vomited a good deal after the operation. She was given large amounts of intravenous glucose daily and nothing by mouth for several days. On the fourth and fifth days there was a considerable amount of bile discharged from the abdominal wound. On the fifth day there was a considerable amount of bile discharged. This drainage rapidly diminished, however, and in spite of repeated dilatations of the sinus with bougies, the bile flow diminished and the sinus closed. She was discharged forty-eight days after the operation. At this time she was mildly jaundiced and there was no bile entering her intestinal tract.

She was again readmitted to the hospital one month after her last discharge. She had been doing fairly well but was still jaundiced and was bothered very much by itching. She had however, gained a pound and three-quarters since leaving the hospital. For the last ten days it had been pos-

sible to feel a mass in the epigastrium which was believed to be liver and interpreted this fact to mean that her liver function had returned somewhat and that she now had a large liver congested with bile. It was felt necessary to make another attempt to see if we could find some dilated bile duct and possibly establish an external sinus which might later be implanted into the duodenum.

Exploration was done on September 24, 1934. The liver was now much larger than at the time of the last operation. After considerable difficulty in freeing up adhesions a fairly good sized bile duct was found deep in a cleft of the liver where the hepatic duct is supposed to emerge. This was opened. It contained bile under pressure and a catheter was sutured into this duct which continued to drain bile profusely. The abdomen was closed.

Four days after operation she was given a transfusion because there had been some oozing of blood from the incision and we felt that it would be a good general therapeutic procedure. About seven days after operation she began to have persistent vomiting. She could eat only very little at a time and any intake of food or fluid caused a marked sense of fullness and pressure in her stomach. It was necessary to put her on constant stomach drainage by means of a small stomach tube passed through the nostril but the patient was evidently losing weight and strength gradually in spite of all efforts.

Jejunostomy was discussed several times and finally as a last resort a jejunostomy was done under local anesthesia four weeks after her last operation. She came through this procedure very nicely and we were able to introduce food and fluid into the jejunum at once with definite improvement in her condition. The bile which drained from her other sinus was also introduced into the jejunostomy. Her jaundice had now entirely disappeared. Fifteen days after the jejunostomy she was able to take forty ounces of fluid by mouth during the twenty-four hours but was still being fed through the jejunostomy and the bile was also being replaced. Four days later she could take seventy ounces of fluid per day with some soft solid food. Six days later she was having fluids in unlimited amounts and soft solid food.

The catheter which was draining bile was connected by means of a glass tube to the catheter in the jejunostomy so that the bile was automatically transferred in this way to the intestinal tract. Eight days later the character of the drainage from the gallbladder wound changed abruptly. Instead of being clear bile it was thin, turbid, milky fluid which seemed somewhat purulent. The next day the catheter in the biliary sinus was changed and considerable gas escaped through the wound and the day after there began to be some redness and irritation of the skin around the sinus. The drainage was bile stained but acid in reaction. Evidently the biliary sinus had ruptured through into the duodenum and we were now having some duodenal leakage through the sinus.

A lipiodol injection into the biliary sinus showed that it connected with the duodenum. The jejunostomy tube had been removed and at this time the tube was also removed from the bile sinus with the idea that the external opening would be allowed to close and hoping that the sinus now established from the hepatic duct to the duodenum would remain open and this is what did happen. Two weeks later the patient was up and walking about. Stools were normal in color. She had gained weight had no external drainage of bile and four days later was discharged from the hospital.

The patient was again readmitted four months

later in April 1935 because of some upper abdominal pain and jaundice. The stools for the last few days had been pale in color. She was kept under observation for two days. Her stools regained normal color and her jaundice subsided. She was sent home.

She has had several of these attacks occasionally with chills and fever and very likely my troubles are not entirely ended so far as she is concerned. Possibly it would have been a better procedure to have done a hepaticoduodenostomy instead of bringing the catheter outside for drainage at the time I found the dilated hepatic duct. She was fortunate in that she developed a spontaneous hepatico-enterostomy and so the situation now stands. I shall delay re-operation as long as possible.

DISCUSSION

DR. DOUGLAS S. ADAMS. In discussing Dr. Sowles' paper I wish to consider the following:

First, the matter of incidence. In going over the literature, isolated cases are encountered but with the exception of Judd's cases an actual series is hard to find. I have not encountered a case nor was I able to find an example in our Memorial Hospital records. Judd has suggested that they rarely reach the surgeon's hands. He is either correct, or as I have concluded the disease in its true form is a comparative rarity.

Secondly, etiology. No one seems to give an answer to this that meets all the requirements. Ransom and Malcolm state that the striking thing in its etiology is the absence of previous abdominal operations and the absence of stones in the gallbladder and ducts. And they further state that it is inferred that even before stones have had a chance to form in the gallbladder damage has been produced in the walls of the extrahepatic ducts. It is difficult to attribute a uniform fibrinosis of the ducts to trauma. I noted that three cases reported gave a past history of typhoid fever. Text books of pathology in describing fibrinous inflammation of the bile ducts speak of possible causative factors as pythiasis, typhus fever, cholera, and malaria. If we consider that some form of gallbladder pathology either existed or was present at the finding of obliterative cholangitis, the cholecystic disease may well be a causative factor. It is to be remembered that, although the blood supply to the gallbladder is separate, its venous and lymph channels communicate directly with the liver and ducts. As Ransom and Malcolm point out, infection ordinarily affects the gallbladder first, with the ducts presenting marked ability to resist infection. But in the rare cases of benign stricture the gallbladder and ducts share alike.

Thirdly, gross and microscopic pathology. All reports agree that the common duct, when found, was hard, small and cord-like in feel. Miller in his report described it as suggesting a thick-walled vein enclosing a number of organized thrombi. Adhesions more or less dense enclose the area making approach difficult. The lumen is usually nearly obliterated, although a small amount of discolored fluid or mucus may be found. Sections show marked fibrinosis of the duct walls, a varied loss of mucosa and round cell infiltrations. An unidentified diplococcus was noted throughout the fibrosed walls in one reported case. In Ransom and Malcolm's autopsied cases besides the chronic inflammatory changes well-marked evidence of activity in the process still appeared. The early cases showed an enlarged reddened liver, the later ones contracted and even greenish in color with well advanced general cirrhosis and generalized intra-hepatic duct involvement.

And finally, in closing, I would like to ask Dr Sowles whether he palpated the common duct at the first operation. It is surprising that such a degree of change could occur in a reasonably normal duct in such a short time as less than two months.

DR CARL MERRILL ROBINSON: I have read and re-read Dr Sowles' paper on Obliterative Cholangitis and I wish to congratulate him, not only on a splendid presentation of the subject, but his superb surgical technique in the case reported.

The case I am reporting, of a type comparable to that reported by Whipple, recovered, in spite of my surgical effort and is a victory for the internist. It teaches a lesson.

J J N, aged sixty three years, was admitted to the Maine General Hospital, January 19, 1929, as a private medical case, under the care of Drs B and B. No significant previous history. For the past sixteen days the patient has had vague abdominal discomfort with increasing jaundice and intense itching. Moderate amount of gas. He has been on a restricted diet, taking eight glyco-tauro tablets a day and local applications for itching. *General examination* negative except for intense jaundice and excoriations from scratching. *Abdomen*, no distention or masses. G B not felt. Liver edge about one and one half inches below costal border. *Rectal examination*, negative. *Urine*, negative except for large amount of bile. *Hgb*, 77 per cent. *Reds*, 4,120,000. *White*, 8,450. *Coag*, 8 min. *Urea Nitrogen*, 13 mg. *B S*, 90 mg. *Stool*, grayish, no mucus or parasites. *Rare R B C*, no W B C. *Occult Blood*, present. *Urobilin*, negative by Schmidt test. *Fatty Acids*, traces only. *Icterus Index* 200. *Van den Bergh* direct and indirect. *Gastric Contents*, no free HCl. *Total Acidity*, seven per cent. *Duodenal Contents*, no bile present. *G I Series*, negative.

Twelve days after admission his physical condition showed no improvement under medical care and his mental condition was less satisfactory. Itching could not be controlled. I saw the patient at this time and felt that exploration was justifiable. Patient and relatives willing to assume the desperate risk. On February 1, 1929, he was explored under novocaine block of the abdominal wall. Gallbladder, buried in adhesions, freed. Not grossly distended but evidently diseased. No gross pathology felt in head of pancreas. Common duct exposed with some difficulty, smaller than normal but identified by aspiration and some bile obtained. Common duct opened and small catheter inserted after failure to pass probe into duodenum. Catheter also placed in fundus of gallbladder. The bile obtained was thin containing much mucus. The liver showed no gross changes. If the patient's cholemia could be relieved by drainage of the common duct, secondary operation could be attempted. His immediate post-operative condition was satisfactory. The first few days there was a small amount of thin drainage but his jaundice did not improve and there was very little change in his general condition for twelve days. Then, active hemorrhage occurred from the operative wound. He was given a transfusion of 500 cc whole blood. Slight oozing continued. Four days later the blood was firmly clotted but bile drainage completely stopped sixteen days postoperative. Movements were clay colored and general health was poor. Duodenal tube inserted into duodenum followed by mag sulph, brought no bile. During the next two weeks, condition improved somewhat on high carbohydrate diet. His wound entirely healed but jaundice persisted and no bile was present in the stools. Up and about. On March 15, seventy-one days after onset, he was taken, by his

family, to Boston to the care of Dr Chester Jones, from whose recent letter I summarize or quote.

"Physical examination showed an intense jaundice, marked loss of weight, a liver two fingers below the costal margin, questionable ascites, slight pitting, edema of the feet and edema of the ankles. Stools were clay colored and there was a little bile in the urine. Laboratory Report, serum bilirubin 4.1 to 100 cc (Diphasic) which increased to 6.9 nine days later. Finally dropped to 0.6, 24 days following on the one hundred and fourth day. On admission, stools showed 1+ bile but on several examinations during the next week, showed no bile. There continued to be no bile in the stool, at times, for over a month. As far as treatment was concerned, he was on as high a carbohydrate diet as he would take from the time I saw him. He was given insulin. His diet consisted of C475 P75 F50. During the first week the patient gained five pounds, was mentally improved but there was no improvement in the jaundice, itching or peripheral edema. Two weeks later his jaundice was distinctly less and stools showed bile. He left the hospital at the end of April, four months after the onset, having been treated by a very high carbohydrate diet, insulin, rest and various symptomatic measures for control of the itching, of which chloral was the most effective."

I have seen this patient personally within a month. He is now seventy years old, in excellent health and has no recurrence of symptoms. The course of this case, subsequent to operation, proved that it was not a surgical problem but the gallbladder buried in adhesions, the presence of bile in the ducts, and my inability to pass a small probe from the common duct into the duodenum, seemed at that time to justify my attempt to drain the biliary tract.

DR T S MOISE, Bangor, Me: I would like to present a case of obliterative cholangitis of the cystic duct that presented some rather interesting findings. The patient was a woman in the early forties, who had a history of a gallbladder disease for several years. I first saw her in September, 1930. She had had an acute attack of cholecystitis a few months prior to that time. At operation, I found that the gallbladder was adherent to the surrounding structures. There was a small pericholecystic abscess. The tissues of the cystic duct were quite friable and the duct was severed by the pressure of a clamp placed upon it.

Examination of a specimen showed obliteration of the cystic duct from the gallbladder down. The remainder of the gallbladder showed nothing unusual. There was no suggestion of a neoplasm. Sections from several blocks taken from the region of the obliterated cystic duct showed a definite histologic picture of malignancy with a marked epithelial proliferation extending from the mucosa to the serosa. Unfortunately, the gallbladder was lost and no further blocks were taken. If there was a carcinoma present, it was probably a small one extending down the cystic duct and the chances were great that a portion of the neoplasm remained in the stump of the cystic duct.

I have a series of slides going through the wall of the gallbladder, in order to show that there is a definite infiltrating lesion with groups of epithelial cells extending from mucosa to serosa histologically indistinguishable from a carcinoma.

I concluded that the patient probably would have a recurrence and fail rapidly. At the present time, five years later, she is in the best of health and I think we are forced to conclude that this was not a neoplasm at all, but an unusually striking degree of epithelial proliferation as is sometimes seen in

The photomicrographs show groups of epithelial cells extending from the submucosa (mucous membrane) in upper right hand corner. Although histologically indistinguishable from carcinoma the findings represent a simple inflammatory hyperplasia in association with an obliterative cholangitis of cystic duct.

inflammatory lesions. You may remember that a striking degree of epithelial hyperplasia with apparent invasion was seen in some of the fatal cases of influenza in the epidemic of 1917 and 1918. I am under the impression that such changes are more likely to occur in those cases in which the destructive lesion was quite severe and there was a destruction of the mucosa as well as the underlying tissue to an appreciable depth. Obliteration of the biliary ducts is more often the result of repeated lesser injuries rather than to such a severe lesion. I think that epithelial hyperplasia presenting a histologic picture of malignancy is unusual in disease of the biliary tract and would like to ask Dr. Sowles if he has seen any marked degree of epithelial hyperplasia in the cases he studied.

DR. SOWLES: Just a word in regard to Dr. Adams' question. There was a very striking change in both the condition of the liver and the common duct between the first and second operations. At the first operation there was nothing remarkable about the liver. The common duct could be easily seen and felt, was of normal size, and apparently not thickened.

At the second operation, the liver was small, very much smaller, with a rough surface, dark greenish

in color, and the common duct as described, a small fibrous cord.

In regard to the other question, I haven't anything to add to the pathology, more than what Dr. Robinson has brought out.

It may be of academic interest to ask whether we can make a diagnosis before operation. I am not sure. The pain, as a rule, is not so severe as gallstone colic, and does not have a tendency to radiate to the back. The jaundice is apt to be more or less intermittent. The presence of fever and chills, of course, means a cholangitis, but does not necessarily rule out a stone. There is usually some bile, found by chemical tests, in the stools.

With regard to postoperative treatment, there are one or two points. We should keep the chemistry of the blood plasma, as near normal as possible. I am thinking particularly of maintaining blood chlorides.

Dr. Robinson also referred to the high carbohydrate diet, which means in the postoperative case, liberal use of intravenous saline and glucose, and the additional fact which was brought out in the discussion, that we can artificially increase the amount of insulin in the blood in order to help the patient burn up the excessive glucose in his diet.

NEW ENGLAND BRANCH AMERICAN UROLOGICAL ASSOCIATION

URETEROVESICAL CARCINOMA CYSTECTOMY—URETEROSIGMOIDOSTOMY*

Case Report

BY WILLIAM C. QUINBY, M.D.†

A MACHINIST of sixty-one years came to the Peter Bent Brigham Hospital complaining of hematuria. This was first seen five weeks earlier, appearing spontaneously and without pain. The bleeding had been continuous, though lately of somewhat diminished severity. There had been no change in force or calibre of the urinary stream and no increase in frequency. Except for a loss of about 5 pounds in weight and slight paleness, he had been well.

On examination, definite pallor of both skin and mucous membranes was evident. The urine was grossly bloody, the hemoglobin 40 per cent and the red blood cell count 2,580,000. The blood pressure was 140/80, the nonprotein nitrogen 31 mg per cent. By cystoscope there was seen a large papillary infiltrating growth in the bladder overlying the left ureteral orifice, attached to this and to the left lateral bladder wall. Inferiorly it extended very nearly to the apex of the trigone. Above, the tumor was sloughing, and here there were also several deposits of lime salts and areas of fresh clot.

Cystogram showed a smooth filling defect on the left side of the bladder 2.5 cm in diameter with an irregular extension laterally. Intravenous pyelograms showed the right renal pelvis and ureter well filled and apparently normal. There was no shadow seen on the left up to seventy-five minutes. This suggested that the tumor had blocked the

left ureter and suppressed the left kidney function.

A transfusion of whole blood was given with benefit and four days later on October 8, 1934, the following operation was performed under spinal anesthesia. Transperitoneal ureterosigmoidostomy, right.

The abdominal cavity was opened and with the patient in the Trendelenburg position the intestines were waited upward, after which an exploration of the pelvis showed no evidence of cancerous metastases. The left ureter was found to be somewhat larger than the thumb, definitely obstructed. The right ureter was normal and showed vigorous peristalsis. Through a vertical incision over it the retroperitoneum was incised and the ureter dissected free to within an inch and a half of the bladder, where it was cut off. Its vesical end was tied and the ureter lifted upward from its bed over a distance of two and a half inches. The retroperitoneum was then closed by interrupted sutures of silk. The sigmoid loop was then prepared by milking its contents upward and downward, and holding it between two Allis clamps, an incision was made about two and a half inches long in one of the longitudinal striations. This incision went through the muscularis down to the mucosa, and the wall of the bowel was dissected backward on either side for about one-eighth of an inch. All bleeding points were grasped with fine clamps and coagulated by the electric current. The upper angle of the incision was then united to the wall of the ureter by a single stitch after which the bowel wall was closed over the ureter by interrupted silk stitches. On reaching the lower end of the incision the ureter was transfixed by a single stitch bearing a curved

*From the Urological Clinic of the Peter Bent Brigham Hospital, Boston, Mass.

Read at the meeting of the New England Branch of the American Urological Association, November 14, 1935.

†Quinby, William C.—Clinical Professor of Genito-Urinary Surgery, Harvard University Medical School. For record and address of author see This Week's Issue, page 266.

needle on either end after which the bowel mucosa was opened again using the electric current. There was no soiling whatever as the lower end of the ureter was invaginated into the lumen of the bowel by passing each end of the transfixing suture and bringing it out onto the surface of the sigmoid. Previous to this a strand of large-sized catgut about four inches in length was inserted into the lumen of the ureter to act as a partial splint. Following this the whole area of anastomosis was buried by a second layer of silk sutures, after which the sigmoid was attached to the retroperitoneum by another single stitch.

On October 26 the patient having made a satisfactory convalescence since the previous operation, a total cystectomy was carried out under spinal anesthesia. The abdomen was opened through the old scar and the peritoneum separated from the surface of the bladder the bladder itself being allowed to remain unopened. By upward traction on the vault, the bladder was gradually lifted out of the pelvis and there was found to be a marked induration and thickening of the left ureter outside the bladder itself. This was unexpected for although this left ureter was not carefully explored at the previous operation, it would seem likely that had it been a solid structure at the site of the previous operation this would have been evident. Continuation of delivery of the bladder was therefore carried out by working from the right side of the organ and on reaching the region of the urethra by the use of the high-frequency cutting current a transverse incision was made going through the substance of the prostate. On reaching the posterior surface of the bladder dissection was made in front of the vesicles. There remained to be delivered then the left ureter and this was dissected upward as far as could conveniently be reached through the present incision, but it was found impossible to extend the dissection high enough to reach any portion of ureter which did not contain evident tumor. This tube was then clamped and cut across after ligation and the bladder removed. Except for this involvement of the left ureter there was no evidence in any piece of extension of tumor tissue outside the bladder. Hemostasis was carefully attended to after which the wound was closed, an adequate drain being left in the depths of the pelvis. The peritoneum was not opened during this operation.

It would seem from investigation of the operative specimen in this case that we have been dealing with an instance of secondary neoplasm in the bladder which has descended the ureter from the renal pelvis above. It was entirely impossible to investigate the left kidney until now. We only knew that it was enlarged and obstructed. I had previously expected it to be a blocked-off hydronephrotic kidney but the presence of new growth in the ureter makes it highly probable that it contains neoplasm within its pelvis. A subsequent nephrectomy is therefore, clearly indicated.

On examination of the ureter in the operative specimen it was found to be double. No previous indication of this had been had, of course because the tumor mass overlaid the entrance of the ureter into the floor of the bladder.

Therefore on November 13 a left nephrectomy was performed as follows. Through a transverse incision under the left costal margin the kidney was exposed found to be very markedly dilated and tensesly elastic to touch. It was impossible to tell what the contents of the kidney might be but it was assumed that they consisted of papillary carcinoma in large part. Investigation of the ureter revealed it to be double and to extend downward

about the size of 3 cm in diameter. The kidney was very hard to mobilize at its upper pole, so the ureter was cut across and using this as traction eventually the whole kidney was freed. Its vascular pedicle was apparently atrophic, the venous supply being single the arterial supply double. After the kidney had been cut away it was found that its contents were only bloody urine, no evidence of new growth being present. Had we been aware of this fact at an earlier period in the operation emptying the kidney would have much facilitated its excision.

Following removal of the kidney the stump of the ureter was carefully dissected out as far downward as the point of previous tying. By chance this laid just over the internal iliac vein so that some care was necessary in freeing the ureter to avoid tearing this structure. Convalescence after this third operation was quite without event and the patient was discharged home on the 25th of November 1934.

Pathological examination of the specimen submitted showed the new growth to be papillary carcinoma. Investigation of the ureter showed that the two ureters joined into a single one just at the junction of the bladder wall at which point there was but a single ureter so that the double ureter was of the "Y" type. It is possible, therefore that the neoplasm originated in the ureteric epithelium near the point of junction of the two thus accounting for its equal distribution into each tube. The ureter as it passed through the bladder wall was also completely filled with tumor. It was very evident on examining the kidney that the neoplasm did not originate in the renal pelvis. We were therefore, forced to believe that this carcinoma was primary in the ureter or bladder the histology being consistent with either. It appears unlikely however that it represents a retrograde extension upward from the bladder and we believe that this was an instance of a primary papillary carcinoma of the ureter originating at the point of junction of the two limbs.

The patient has done very well during the year which has passed since operation. At his last visit he was found to have gained weight to have normal strength and the nonprotein nitrogen was 41 mg. per cent. He passes urine by rectum about once in three hours and once at night.

AN HYPOTHESIS FOR THE ORIGIN OF RENAL CALCULUS*

BY ALEXANDER RANDALL, M D †

WHEN one undertakes to explain the origin of stone in the upper urinary tract, one appears to be confronted by the fact that our theories of today seem to be increasing the complications of the picture rather than its simplification. Yet, when one tabulates the five prevalent theories relative to the causation of renal calculus, it is interesting to find that, in spite of their wide divergence, they are after all rather closely interrelated. It is essential, when attempting to solve any complex problem, that *cause* be put to one side and *effect* to the opposite side, and it is to be my present effort first to try to clarify this point of cause and effect in our present knowledge of renal stone and then, if a plausible cause for stone be found, to see if the subsequent effects are in keeping with the hypothesis for its origin.

First of all, let us be cognizant of what has happened in our understanding of stone in the lower urinary tract. For centuries considered a disease entity, and operated upon with what surgeons thought success, bladder stone is now looked upon as a symptom and not a disease. There is not a surgeon today but will finish an operation for the removal of stone from the bladder without appreciating that it is a resultant effect and without looking for its cause. Prostatic obstruction, diverticulum, fistula, tumor and ulcer are looked upon as the primary reasons for the formation of such a vesical calculus, and the prevention of its recurrence will depend upon the successful removal of the individual cause.

How often is the surgical problem of a renal calculus approached with a similar understanding of the fundamental pathology? How often, in the course of a difficult exposure, is a causal obstructive factor looked for and corrected? And how often, after the removal of a renal calculus, are steps of a prophylactic nature taken, both at the operating table and during the postoperative convalescence, to safeguard the patient against recurrence? In other words, do we approach every case of renal calculus looking upon the stone as an effect and, in each case, attempt to find a cause? And have we transported our knowledge of the recognized causal factors of stone in the lower urinary tract to an appreciation of what must be similar causal factors in the origin of stone in the upper urinary tract? I think we should have ceased

long ago to lecture, write papers and even publish books under the title of "Calculus Disease", for stone in any part of the urinary tract is but a symptom and not a disease entity.

Etiology—Let me briefly review for you the five theories which are current today as reasons why a kidney becomes encumbered with a calculus, and at the same time point out their close relationship.

1. Unquestionably, priority belongs to the dietary theory. This causal factor comes to our attention from two separate angles. First, and perhaps of the greatest importance, is the realization that stone of the bladder in childhood has almost disappeared from the picture of surgery. Fifty years ago (and for the period antedating this) it was found in civilized countries as a dominant factor in "calculus disease". It has been pointed out that in England, in 1800, forty-five per cent of the cases of vesical calculus occurred in children under fourteen years of age. In France over half of the cases of stone in Civiale's clinic were operations on patients under twenty years of age. In England, France and America this picture has so changed that bladder stone in childhood is today a rarity. And the only factor to which we can point, as bearing upon the disappearance of this surgical condition, has been a liberalization of the diet of childhood. Children today are fed from infancy on a diet which would have made our grandparents shudder, and this is to be compared with the picture of stone in childhood which still persists in its prevalence in the surgical clinics of the countries where the dietary is still of a variety exceedingly limited, as it used to be in Western Europe.

The second point under this theory has been the proof that diets deficient in vitamin A are exceedingly prolific of stone formation. The reason given is that such a diet causes certain changes in the epithelium of the urinary tract, which is termed "keratinization". Two things are significant. First, that such stones are consistently formed of calcium-magnesium phosphate, and secondly, that in experimental animals where stone has been so produced, such concretions have been made to disappear if the diet is changed to one rich in vitamin A. Here it seems we can clearly see cause and effect.

*Read at the meeting of the New England Branch of the American Urological Association November 14 1935

†Randall Alexander—Professor of Urology University of Pennsylvania School of Medicine. For record and address of author see This Week's Issue page 268

- 2 The second theory which enters this picture is that of infection. It has been said that if every case of stone were searched to its ultimate end an infection would be found underlying it. This is probably an overstatement, but, nevertheless, infection unquestionably does play a very definite part in the formation of some stones. There are numerous instances and examples to be cited in relation to this theory, but let me recall to mind Rosenow's work and also the observation of the frequent occurrence of renal calculus in the chronic ostomyelitis cases.

Again, two things are of great significance as regards infection and stone. First, the concomitant frequency of infection where epithelial changes due to vitamin A deficiency predominate with the interrelationship of these two theories, and secondly, the role that infection frequently plays as an etiological factor in the recurrence of renal stone. The rôle of infection should also be broadened to include those cases of encrusting cystitis and the encrustations about urinary fistulae. Here an infecting organism is looked upon as being responsible for the breaking down of urea into ammonia, causing an alkaline urine with the subsequent precipitation of urinary phosphates. It is pertinent to my theory that I again call attention to stone as an effect and to an infection as part of the cause.

- 3 The third theory is the effect of stasis and faulty drainage. Long a recognized factor in the lower urinary tract, it must likewise play a definite part in the etiology of certain stones in the upper urinary tract. Stone has been frequently watched during its period of actual growth, where partial occlusion of ureteral lumen has produced faulty drainage. Stone has been found in a relatively high percentage of cases where individuals have been bedridden, such as in the care of generalized disease, in the immobilization for fractured bones and in the care of cases with tuberculous lesions of the hip and spine. All these conditions are related to faulty renal drainage and, in addition, are frequently associated with chronic infection and yet again with the recognized decalcification of the bony skeleton and the loss of calcium during long periods of complete muscular inactivity.

Again, let me accentuate the close interrelation of these three theories: diet, infection and faulty drainage. It is neither a constant fact nor is it necessary to expect that every kidney pelvis which is poorly drained, even if also infected, must form a stone. Such is quite comparable

to the incidence of bladder calculus as an accompaniment of prostatic obstructions. The failure of stone development in cases where the ideal morbid set up is waiting is one of the strongest facts that we have to present in the realization that our present theories are not sufficient. They may be factors but not basic etiological facts.

- 4 Our fourth theory is that fascinating one of disturbance in the colloidal mechanism of the urine which plays a very important rôle in the body's normal ability to eliminate insoluble crystalloids in a supersaturated solution in the urine. It is pictured that the urinary colloids carry on their surfaces insoluble urinary crystalloids by what is termed "adsorption." The normal daily amount of the colloid is sufficient for the elimination of the normal daily amount of the insoluble crystalloids. That these urinary salts are present in a supersaturated state in the urine is an important fact, both as regards the function of the colloids and as bearing on the precipitation of the salt when stone forms. For, if one disturbs this so-called colloidal balance by either increasing the crystalloids or decreasing the colloid surface area, there then occurs a precipitation of the crystalloids and their appearance in the urine as actual insoluble material.

Stripped to this simple viewpoint, again let me call to your attention the interrelation of this etiological theory with the three previous ones. For, first of all infection with its morbid products, and epithelial degeneration as from a vitamin A deficient diet, are both recognized as reasons for a disturbance of the normal colloid mass, and wherever there is an increase in crystalloids, such as occurs in decalcification of the bony skeleton, we see the opposite picture of an attempt being made to eliminate more crystalloids than there is assumed to be colloidal surface to hold them in solution. Therefore, these four theories of stone formation although each may not be constant or sufficient, are nevertheless very closely interrelated.

- 5 Our fifth theory is the recent one, where it has been pointed out that disease of a hyperplastic character in the parathyroids is responsible for decalcification of the bony skeleton and the occurrence of an actual calcium diabetes in the urine. As a result of the studies made at the Massachusetts General Hospital it is claimed that this factor is present in ten per cent of all cases of renal calculus. Here we are unquestionably getting beyond the urinary tract and finding a causal factor of utmost importance. But

when we concentrate our view upon the urinary tract, such hypercalcaemia is not of itself a factor that produces a stone. It works in well with the theory of colloidal imbalance, for here again we picture an excess of crystalloids over and above the surface-holding power of the colloids, and as such, this theory of a reason for stone works in with the four previous ones as an interesting factor but not as an actual initiating lesion.

There seems to be a broad gap between the theoretical mechanism for possible stone growth in a renal pelvis, and our accurate knowledge as to why a stone came into existence. I can see reason in these various theories on the etiology of stone that can be of importance as to how a stone may grow, but none of them, to my mind, give a satisfactory reason as to why a stone does occur, where it starts, how it actually originates and why it is not washed away when still microscopic. It is particularly significant that no one of these five theories can be depended upon to produce a calculus in anywhere near a one hundred per cent of cases. We seem to have a plethora of theories and a paucity of facts. In the first place, it is no unusual thing to watch a patient with a chronic phosphaturia, a chronic oxaluria, or probably most interesting of all, a chronic cystinuria, in whom, in spite of the persistency of this perversion of the normal, a stone does not form. Secondly, we must realize that when a stone does occur in the renal pelvis, it virtually always starts as a unilateral lesion. Thirdly, as no one of these theories is infallible in the production of stone, so also the control of no one of them is of unfailing virtue in the prevention of the recurrence of stone. It is thoughts such as these which make me feel that these five theories, concerned with the etiology of stone, are all essentially secondary reasons, and none of them can be classed as a primary cause of stone formation. Nevertheless, they are of the utmost importance, even as secondary reasons, when one takes up the subject of the prevention of recurrence, for as such, each one has to be removed from the picture, or it remains as a potential invitation to the growth of a recurrent stone.

The *difficult part* of this problem is to fit into these etiological theories the *known variation* in the actual chemical character of the stone itself. Such concretions are known to be formed from calcium oxalate, calcium-magnesium phosphate, calcium carbonate and calcium-magnesium-ammonium phosphate. Again, sodium urate, ammonium urate, uric acid and the rarer salts of cystine and xanthine are found. It is easy to see that a disturbance in the calcium metabolism can very readily be a factor in the

growth of a calcium stone, but there it must end, and certainly could have no relationship to the formation of a stone of uric acid, a urate or one of the rarer salts.

It has been the existence of this multiplicity of theories, with the known divergence of stone chemistry, that has made it difficult for anyone to grasp or formulate a theory for stone formation, and this difficulty, I am sure, has been a reason why surgery has adopted the unfortunate middle ground of speaking of stone disease as an entity and, by so doing, losing all sight of etiology. Such a point of view has, of necessity, made it impractical to adopt any steps toward stone prevention and has led to the regrettable surgical attitude of removing a stone with a clean conscience and with the feeling that the entire surgical lesion has been corrected.

For the past few years I have attempted to explain the inconsistencies in the formation of a renal calculus by trying to separate the picture according to the chemical composition of a stone. This is to say that one would make a separate chapter according to the chemistry of a stone and then try to write into that chapter a causal factor and perhaps elaborate further on diagnosis, on treatment and on prevention. In some of our pictures this has not been so difficult to do. The stone which follows a vitamin A deficiency has been shown to be consistently formed of calcium-magnesium phosphate. The stones which follow hyperparathyroidism have likewise been of a definite chemical character and always a calcium salt. Again, those stones which form in the presence of an infection, which produces an alkaline urine, have been consistently a triple phosphate deposit.

But, there has been one very definite stumbling block which this mode of approach has not explained, and that is the occurrence of a laminated stone, in which might be a core of uric acid, a second lamination of urates, a third layer of pure oxalate crystals and even a fourth deposit of calcium-magnesium phosphate. The failure to explain these phenomena has caused me to set aside the pure chemical theorization and to approach the story of stone from a new angle of thought.

Let me present this hypothesis in very brief form. I believe there are but two basic causal factors which are capable of initiating the development of a stone in a renal pelvis. The difference between these two causal factors can be sharply delineated, the resultant stone shall be termed a "primary" or a "secondary" renal calculus, dependent upon which of these two causal factors is present.

In the *first class*, or the "primary" renal calculi, one finds those cases in which the clinical picture is especially clear, and every physician

has experienced such a case in his practice. To it belongs the individual in otherwise perfect health, who is suddenly seized with the clinical state known as calculus colic. Examination finds a man in the throes of renal colic due to a calculus measuring up to a centimeter in size, which has suddenly entered the upper ureter and has obstructed the same. X-ray reveals a shadow just opposite the lower pole of the kidney. Urography proves this to be a calculus lying in the ureter, and behind it a normal pelvis that is just beginning to show the evidences of back pressure.

As I say, this clinical picture is unquestionably familiar to everyone and one stops to ask these questions: What caused that stone? How long has it been growing? Where has it been? And why has it suddenly produced this severe clinical picture?

An answer to these questions I believe to be not difficult of formulation. It is my firm conviction that such a calculus has arisen as a gradual crystallization upon a lesion in the renal pelvis. Somewhere in the renal pelvis, most probably on a papilla, or in the papillary-calycal angle, there has occurred a primary ulcerative lesion. It is of small size but with a raw surface, and thereon has occurred, through one of the above theoretical reasons, the precipitation and coalescence of urinary salts. Following the colloidal chemical theory, the salts so precipitated are those which at that time are especially supersaturated in the urine. As such the deposit starts, and once started, has every reason to gradually increase in size. Being so fixed, it gives no symptoms of its presence until, due to some factor be it trauma, size, weight or sudden motion, it ceases to be a fixed concretion and breaks loose from its point of origin. The next natural course is nature's effort to extrude the calculus, and such extrusion means passage down the ureteral line of drainage with the result that one sees the patient in acute ureteral stone colic.

A stone of this type has interesting peculiarities, both on the x-ray plate and on examination with a hand lens after its removal. It is frequently heart (or arrowhead) shaped, or else a long oval, and is characteristically of a single salt deposit. The heart-shaped stone is generally smooth with a rounded point, while the ovoid stone has a highly crystalline surface and one end, though evenly developed, shows sharp crystal points. But the opposite end of either variety shows every evidence of having been a point of mural attachment. One can visualize how such a stone crystallized upon a basic papillary or calycal, ulcer, how from such an origin further crystallization augmented growth, how it remained silent because fixed, how its shape originated, and so it developed

in an otherwise normal pelvis, until its size allowed of its being no longer adherent.

One thing remains to be explained, and that is the primary initiating lesion. Here it is my feeling that primary papillary or calycal ulceration is of much more frequent occurrence than we have been led to suppose or even made to think. Such ulceration could be either infectious, trophic, or allergic. In the past our pathologists have routinely examined kidneys at postmortem by opening them from the convex surface in toward the hilus. As you well know, it is infrequent that the pelvis is thus competently opened or, if subsequently cut, is completely searched. You cannot find in the textbooks on pathology of today any mention of any pathological condition occurring in the renal pelvis other than the generalized one of pyelitis or the very self-evident one of tumor. The finer pathology of the renal pelvis has yet to be written. I would like to mention the brilliant work in this respect recently published by Lieberthal and von Huth, in regard to the early pyelitic lesions in renal tuberculosis. The facts demonstrated by them in renal tuberculosis are pregnant with possibilities in regard to the more frequent occurrence of pelvic ulceration in other infectious states.

In the *second class* belong the calculi which form in a renal pelvis in which urinary stasis is present because of some obstruction to the normal urine outflow. Examination by urography reveals the presence of hydronephrosis, and the stone grows as a complication of such a static condition. It has been the tendency to look at this picture in a reverse order, making the stone the cause of the hydronephrosis, rather than the resultant effect or complication of a hydronephrotic pelvis. Such stones are frequently found actually floating and freely movable in their habitat. They are nearly always smooth and round, sometimes multiple and faceted, and frequently laminated, being composed of different urinary salts. To me this picture is so closely akin to the recognized condition as seen in vesical calculus that it should need no further exposition.

As the first class, which form as crystallizations upon pelvic ulceration, are termed "primary" renal calculi, so this second class, postulated upon faulty pelvic drainage, are called "secondary" renal calculi. The actual origin of the "secondary" renal calculi demands nothing more for a nucleus than a cluster of desquamated cells, a bacterial clump or a tiny clot of blood. They are as easily assimilated into our clinical pathology as the familiar vesical stone, and on equally parallel lines runs the observed fact that when all the essential factors appear to be present for a stone's growth, it does not, of necessity, materialize.

It remains to be explained why those stones, which are now termed "secondary" are fre-

quently found to be formed of varying chemical laminae. This occurrence should almost be expected rather than, of necessity, be explained. There is no doubt that, in such a supersaturated liquid as the urine, certain salts, at certain epochs, reach the threshold of their insolubility and precipitate in pure form over a period of time. Under these conditions there will be periods when one type of salt will be more easily precipitated than others, and the laminations will correspond to exactly such periods. Likewise, it is to be recognized that the growth of such stones can and does vary according to the type of deposit then being made, and we are all cognizant of the slow growth of the uric acid and urate stones, as compared with the rapid growth of the earthy and triple phosphate stones. The factor of supersaturation of a urinary salt becomes of greater consequence the more we dwell on these facts and, as such, lends greater weight to the rôle of colloidal chemistry.

Discussion—The problem of renal stone has been before the medical profession long enough for us not to know more positively its cause and its prevention. The problem is a complicated one and the effort to simplify it to a single given causal factor has undoubtedly led to delay in understanding, to multiplicity in theories and to disappointment in results.

As might be surmised, there are border-line cases and long-standing complicated cases whose explanation is buried in a confusion of pathology. It has been my purpose to look upon the simple case, the one without complicating elements, and by so doing try to see behind the scenes at birth. Such has led to the conclusion that some stones arise in what we would call a normal shaped pelvis and one whose damage is to all appearances perfect, such I have termed "primary" renal calculi, others are found in pelvis which, for various reasons, are suffering from faulty drainage and such I have termed "secondary" renal calculi.

I have tried to present an argument that our present theories explanatory of the cause of renal calculus fail of their purpose and likewise do not answer pertinent questions in regard to the clinical course of the disease. For these reasons I have placed them in the category of important but secondary causes.

The theory of vitamin A deficiency, that of colloidal imbalance and that of parathyroid adenoma, play important rôles only in deciding the chemical composition of a calculus.

The theory of stasis stands, when such can be demonstrated to exist, and in such cases the presence of a calculus is to be considered a secondary and complicating factor of the stasis. The laminated calculi will be found in this group, as likewise most of the multiple stones, the large solitary stone, and the silent renal calculi.

The rôle that infection plays is twofold. In the case with stasis it enters as simply another contemplating factor to the pathological and surgical picture. That infection plays a far more important rôle in the causation of minor papillary or calyceal lesions in kidneys that are otherwise normal, and by so doing creates a focal point on which crystallization starts, is the crux of my hypothesis. It has been outlined how such stones may be recognized and it has been suggested that such should be termed "primary" renal calculi. There remains to be discussed the likelihood of such minor lesions. Experimental work carried on during the past three years in an effort to produce such minor lesions has been extremely difficult and bitterly disappointing. Trauma, electrical fulguration, chemical burns, and early lesions of vitamin A deficiency animals have been studied without conclusive results. The experiments of Rosenow suggest the rôle of distant focal infection and in clinical cases it has been sought and has been constantly found with startling consistency. The work of Lieberthall and von Huth, already referred to, in which they sought and demonstrated minor papillary or calyceal ulcers in early and in extremely latent cases with tubercle bacillus, confirms the idea of incipient pelvic lesions in blood borne infections. The spontaneous occurrence of the Hunner ulcer of the bladder (studied pathologically by Allen J. Smith and called by him "pan-mural cystitis"), long recognized as an example of suspected metastatic infection, is another analogous lesion, and it is likewise pertinent to recall the familiar occurrence of the precipitation of salts on various ulcerative bladder lesions. When we add to these possible factors in the field of infection the additional possibilities of circulatory troubles, of metabolic diseases, and of allergic reactions, it seems safe to surmise that pelvic lesions do, and must occur, in greater frequency than at present suspected. Fenwick's papillitis is another case at point. We have had the privilege of studying four cases where frank renal hematuria was clearly attributable to allergic reaction to food products. Such bleeding must of course have been accompanied by actual papillary or calyceal lesions and is recognized as belonging to the interesting group of anaphylactoid purpura. This adds just another possibility to the minor lesions of the renal pelvis wherein if the conditions be right, calcification could properly follow.

The hypothesis offered is that upon such a lesion crystallization of a "primary" renal calculus first takes place, and that its chemical character depends upon the salt in the urine, which at that epoch, is the most supersaturated one.

Therapeutic Deductions—Of the "primary" stones the vast majority will be found as uric-

teral calculi, though some, of course, get no further than the true intrapelvic junction. If our deductions are acceptable, their actual origin depends upon extrarenal causes. For accentuation one is tempted to put them down as due to prerenal causes.

Today I am trying to study every case of "primary" renal stone as one would study an arthritic—search out focal infection, look for allergic reactions, think of dietary habits and make the necessary laboratory studies for metabolic disorders, for in such I believe both the cause and the prevention of recurrence are to be found. The persistent stone former is a perfect laboratory for active research in this subject. There is a pet theory among some that patients go through a stone-forming age and that, once beyond that age, they cease creating further stones. I would like to suggest that in all probability, the intercurrent removal of an infected tooth, a bad gallbladder or some other chronic focal infection had much more to do with the cessation of the stone-forming habit than the mere passage of the years. Focal pelvic infection must be combated by every active means at our disposal, but in addition let me urge that the patient be studied as a whole and with the intention of ruling out every possible prerenal factor that may play a part.

The "secondary" calculi, on the other hand, present the real surgical problem. Here the lithotomy is but a step in the proper surgical handling. Keeping ever before us the pitfall of bladder stone, let us approach each and every case of "secondary" renal calculus in exactly the same spirit making the stone of secondary interest, as compared with the acute problem of correcting the primary hydro-nephrotic state. Here the cause is always intrarenal (intrapelvic), and it is beyond the scope of this paper to discuss the surgical possibilities. But if the correction of faulty drainage is not definitely and satisfactorily obtained, let me advise the removal of the kidney, for recurrence of stone is almost a certainty.

The final word on the prevention of the recurrence of "secondary" calculi was said long ago (and then in regard to vesical stone) that nothing short of perfect drainage of the pelvis and sterilization of the same will give any assurance of success, and let me add that this is at times most difficult to attain.

DISCUSSION

Dr. JOHN H. CLEVELAND. I am greatly impressed with this broad conception that our guest has taken in regard to the etiology and treatment of renal stone. As I understand him, he includes five possible causes and he attributes the formation of stone to one or more of them but to a possible combination of any or all of them. This broad point of view means advancement in the understanding of this subject. While he accepts the two causes that we have all been brought up with that is, stasis and infection

he emphasizes what we have more recently been hearing about deficient vitamin A diet, and includes recent knowledge in the field of endocrinology and the chemical condition of the urine as well as focal infection as possible etiologic causes. That he has dealt with those various factors and made a correlation of one or more or possibly all of these factors, is a rather new and broad point of view which I think is a somewhat new interpretation, and is to be commended. His consideration of the therapeutic measures at our command takes as fundamental the overcoming of stasis and infection when it exists. This is something that we have long appreciated. His attitude regarding the proper diet and the other two metabolic factors those that have given knowledge from a better understanding of endocrinology and the chemical composition of the urine as well as seeking focal infection in various structures of the body are relatively new and indicate that progress may be made along these lines. His attitude in regard to diet is substantiated by the experimental work of Grossman and that of Osborne and Mendel as well as the recent communication of Higgins which this society had the pleasure of hearing. His correlation of this information with the other factors that he has mentioned, seems to me to be the best interpretation and with further work along these lines that Dr. Randall indicates, may well be helpful not only in bending existing stone but in connection with its prevention and recurrence. Personally I have received much information from the communication and wish to add my word of appreciation of what Dr. Randall has brought to us this evening.

Dr. WILLIAM C. QUINN. *Mr. Chairman Gentlemen*—It has been a great pleasure to listen to Dr. Randall's theories as well as his knowledge on this urologically universal subject of stone formation. I am glad that he takes the point of view that stone formation is not a disease entity but rather the result of a temporarily abnormal state of the body. I know Dr. Randall wishes us to visualize the kidney as an organ which has various states of being according to those of the body in which it lies. A persistent body state such for instance as occurs in deficiencies of diet, must inevitably have an effect on the kidney. From the physiological point of view the kidney first liberates from the blood stream a fluid of the same constituents as the blood serum minus its albumin. Following this before the urine is propelled into the pelvis, there is absorption by the tubules of certain constituents which the body cannot afford to lose but which must be eliminated through the glomerulus because otherwise filtration would not be possible according to normal osmotic laws. Therefore we have the problem not only of filtration but also of absorption which produces concentration. So the crystalloids and colloids found in the urine are in some instances much more concentrated than they are in the blood stream from which the urine is made. This means that the kidney normally is a labile organ which must be constantly shifting its various activities to compensate for the various changes in composition of the blood flowing through it.

It is conceivable that inability of this absorptive or concentrating power of the kidney at one time or another and for reasons as yet not understood leads to the upset of the colloid and crystalloid balance of the urine with resultant formation of stone. We know something about infection and stasis as factors in stone formation. Vitamin deficiency we are beginning to know something about. The intimate chemistry however of the causation of stone has not yet been elucidated.

It is not inconceivable that we may later find in

the kidney an analogous situation to that for instance which occurs when some anesthetics are administered. Here chemical reactions occur in cells of the body, especially those of the brain, which are reversible. It is probable that a solution of lipoids occurs which, after the anesthetic has been removed, reverts back to the normal condition. Possibly a similar chemical reaction may occur in the tubule cells of the kidney under circumstances as yet unknown. Certain factors may conceivably depress them at one time, forbidding or at least interfering with normal absorption from the glomerular product, at another time allowing normal absorption to continue. In this way, it is fairly easy to see how the colloid balance of the urine can be temporarily upset.

These remarks are at present entirely theoretical and have no practical bearing at the moment. Nevertheless, we are learning more and more about stone formation, due to such analysis of the subject as has been so ably given us by Dr. Randall tonight.

DR FULLER ALBRIGHT, *Mr. Chairman, Dr. Randall, Members of the Society*—I am very much indebted to this society for inviting me here tonight and giving me an opportunity of hearing this very interesting presentation. Dr. Randall brings up the question of what keeps the stone in the kidney until it is large enough to be a stone. He offered a very interesting suggestion as to what that may be. My work at the Massachusetts General Hospital neither confirms nor disproves this hypothesis. Certain facts I do know.

We have had twenty-nine cases of proved hyperparathyroidism at the Massachusetts General Hospital and nineteen of these had kidney stones. If one allows for the four cases of bilateral stones, of the fifty-eight kidneys in these twenty-nine patients, twenty-three had had kidney stones, about 40 per cent. We also know that in hyperparathyroidism there is a marked increase of calcium and phosphorus excretion in the urine. We know that these stones are made up largely of calcium phosphate. It is not too much to assume that the reason that this group of patients, as opposed to another group of patients, has stones is because the individuals of the group have an increased amount of calcium and phosphorus in the urine. In other words, whatever is happening in most cases of kidney stones, it would seem that in these cases the one factor is that they have too much of something in their urine. I doubt that there is any other factor in these cases which would not be present in normal individuals. If these stones in hyperparathyroidism are primary stones and the theory of Dr. Randall is correct, it would seem that normal people have about a 40 per cent tendency to have ulcers in any one kidney and would have about a 40 per cent chance of forming stones in any one kidney if they had hyperparathyroidism. That, at first, seems rather unlikely. On the other hand on looking at these pictures of Dr. Randall's, I can see one possibility of the above reasoning being incorrect.

As we study these cases of hyperparathyroidism we notice that many of them show phosphate casts in the urine. These casts are all formed in the collecting tubules. Most of them are formed at the papilla, just where the tubules enter the pelvis of the kidney. As you see them in sections, quite often the cast becomes attached to the papilla and it is not unusual in x-rays to actually see calcium deposits in the papilla, right at the end. If you picture the calcium phosphate cast being located at the end of the papilla, it might start a little ulcer. There might be an increased tendency, therefore, for ulcers in these cases. That would bring

our experiences in line with the hypothesis of Dr. Randall.

Our studies at the Massachusetts General Hospital have all started from our interest in hyperparathyroidism and we have tried to see whether what we have learned in that condition might not help us in the study of stone formation in general. This question came to our minds. In hyperparathyroidism we believe the one predisposing factor is the increased amount of calcium and phosphate in the urine. How much increased is it? It is not any more than twice as much, if that, as you get by drinking a lot of milk at any one time. The point I wish to bring out is that the amount is not so extraordinary, but that an individual in his regular diet might pick such a one so that the net result as regards the composition of his urine would be comparable with hyperparathyroidism. We believe more and more the theory that increased crystalloids in the urine are the primary factor in most cases of stone formation. This is probably true of the calcium phosphate stones of hyperparathyroidism, of the cystine stones of cystinuria, of the uric acid stones of gout, of the phosphate stones of the milk drinkers. Why isn't its application even more general? As we study the various stones, most of them are phosphate stones and phosphates are a very common substance for people to take. If they take a large amount of alkali at the same time, as with the Sippy régime, they get the ideal background for the precipitation of these stones.

In conclusion I would say that I have no information as to how the stone actually gets started. I repeat that it is my guess that the reason why some people get stones and others don't is because they have a change in metabolism or a peculiarity of diet which results in their having more crystalloids in their urine than can be held in solution. In the case of phosphates, this may be due, not to an increase of phosphates, but to a lack of acidity of the urine.

DR. J. DELLINGER BARNEY: After hearing this interesting paper of Dr. Randall's, I am sure it is a most difficult thing to discuss a subject like this in the face of all we have heard tonight. We are beginning to recognize that the subject of urinary lithiasis may be classed very well with cancer or tuberculosis. I think we all recognize also that urinary lithiasis seems to be regarded not as a disease so much as a symptom of something wrong, either locally or generally. Just what that is, we are all trying to find out. Dr. Randall has spoken of all these various theories and I am very much interested and very much impressed by the clarity with which he has told us about them.

Without being critical, I want to ask questions, simply because it might help me to get a little more light on the subject.

In regard to stasis, how many cases do you see with stone as compared with stasis without stone? How many cases of infection of the kidney without stone as compared with those with stone? If it is a vitamin or dietary disturbance, why do we get stones only on one side and not necessarily on both sides, because presumably that dietary deficiency affects one kidney quite as much as the other? How many cases do you see of focal infection, teeth, tonsils, sinuses or whatever, with stones, as compared with the numbers of patients you see without stones? I am not trying to explain this, I am just pointing out what we all acknowledge to be the facts. In regard to hyperthyroidism, with which I am a little more familiar, it is a little difficult to see how or why, after removal of the parathyroid gland, and the passage of the stone or its removal, stones do not recur so far as we know. Infection is still there, the diet perhaps has not

changed and the conditions are not essentially different or at all different from what they were before and yet stones do not recur. Even if there is an excess of calcium in the urine the stones are more often unilateral than bilateral. It is a peculiar problem and I don't know any better way to get at it than along the lines Dr. Randall has suggested, namely that we must get the pathologists to study the kidney with a great deal more minute care than heretofore, hoping that we may find some of the lesions which Dr. Randall has described and also it seems to me we might well profit by the more intensive study of the average normal patient. That may be theoretical but if we could theoretically take a group of people and keep careful record of their urine from a chemical standpoint varying with the diet, we might throw some light on the subject.

After a good deal of thought, without doing very much about it because it is hard to know what to do, I have come to the conclusion that after all it is a question for further metabolic study, further dietary, endocrinological and physiological study. It doesn't matter whether you, our physiologists or chemists do it, but I think along these lines we may eventually find the answer to this problem.

Dr. G. G. SMITH: I would like to ask Dr. Randall what would happen if he gave these men uric acid.

Dr. EDWARD J. O'BRIEN: I would like to speak of a very interesting case of a child three months old that had renal calculi. I saw this case a couple of months ago at the Cambridge City Hospital. The child was brought to the hospital and sent to the Pediatric Service and was diagnosed by the pediatricians as marasmus and a severe gastroenteritis. The child did not do very well but died. At autopsy, among other things was discovered the presence of multiple calculi in the kidneys. Dr. Timothy Leary, pathologist at the hospital in his report of the autopsy states: "The kidneys combined weight was 36 grams. On section they presented grayish pink surfaces with normally prominent pyramids. Cortex was .2 cm. wide. Capsules stripped readily to reveal lobulated grayish pink smooth surfaces. Pelvis and ureter on left normal. In calices and pelvis of right kidney there were numerous small solid yellow calculi less than 1 cm. in diameter. Ureter normal."

He further reports: "Received several pinpoint brownish calculi together with two which measure approximately 1 mm. in largest diameter. Surfaces smooth and slightly rough. Tests of oxalate, calcium and phosphates were negative. Uric acid was positive."

This was an undernourished child and was probably a case of vitamin A deficiency and that was probably the reason for the formation of these calculi.

I report this case because I feel that we probably would find more calculi in these infants if search was made for them at autopsy.

Dr. CLYDE L. DEMING: I would like to ask Dr. Randall two questions. His theory of papillary ulceration is an interesting observation and he offers three theories for this infection atrophic lesion and allergic lesion. I would like to know if he has considered the theory which Dr. Cushing stated some time ago when he noticed that in brain lesions, especially of the base, certain ulcerations occurred in the stomach and in the intestines, these ulcers being epithelial ulcerations of an acute nature. Recently Parker has described in his work on injury to the thalamus and ulcerations of the epithelium of the stomach and in the intestine. Recently we have had at least fifteen autopsies with injuries to the base of the brain followed by acute ulcerations and perforations of the stom-

ach and intestine. Might not then some brain lesion have a bearing on the ulcerations of which Dr. Randall speaks?

The second question is based upon Dr. Loew's work, which shows that stimulation of the vagus has produced an aceto-choline substance which causes ulceration of epithelial surfaces. Since the autonomic system has now been demonstrated to run in the base of the brain may it not be possible that some stimulation of the nerves causes that nerve to secrete a substance which would produce a localized ulceration of an epithelial surface such as the calyx of a kidney?

Dr. RANDALL: I came to Boston with the expectation of a keen discussion of my subject and I have not been mistaken in my interpretation of the New England Branch and thank you for the generous way in which you have given me your reactions and ideas. I have attempted to present this subject from a purely clinical point of view. I have studied sixty-seven recent cases (twenty-three of renal stones and the remaining ureteral stones) in an effort to establish some relationship to the theory of pelvic pathology as a basis for initiating lesion. When I say ulceration I do not mean that it has to be infectious, trophic changes, infarction, perhaps, may play their parts. That focal infection does play a rôle I know because it has been interesting to see how regularly something real in the way of an acute infectious process has antedated the symptoms of primary stone by something under two months. I know the clinical aspect is a poor way to present a subject to prove anything but if you seek it, that infectious side is too constantly present to overlook and when we come to the question of prevention I am certain it is to be eliminated as one of the most frequent causes of recurrent calculi.

I was delighted to hear Dr. Deming. I said the finer pathology of the renal pelvis has yet to be written.

I have been especially interested in Dr. Alhright's work but he answers his own question, for I do not mind if the tubules are congested with precipitated salts, they must come out from the tubules on the papilla, causing trophic changes and further crystallization. Of course his picture is on one side only that of calcium phosphate and it doesn't enter into the picture one iota if uric acid calculi are present. Being so consistently calcium phosphate it doesn't even touch the calcium carbonate stones which have run much higher than any other salt in our chemical analysis of stones in over 250 cases. It apparently doesn't enter into calcium magnesium phosphate stones or the triple phosphate ones. I think the chances are that in the parathyroid picture the early lesion is a papillary erosion. You must realize that you can have inflammation and ulceration without infection. Those pictures I showed of our rat experiments in vitamin A deficiency reveal a clear-cut ulcer but no infection.

Dr. Cunningham brought out a point I am glad to answer. That is, in the prevention of stone in the group I have classified as primary I suggested in the paper that they can almost be called prerenal because their primary trouble is due to something out of the kidney. Therefore, prevention consists of the removal of the stone and then immediately you have to take steps to prevent recurrence by a close analysis of your patient from every one of those different angles, focal infections, metabolic studies, perhaps allergic reactions, etc.

Dr. Barney asked for some figures. I can give them to him. In twenty-seven cases of renal calculus found in the kidney pelvis or above the ureteropelvic junction I could class but three of

them as primary I showed you pictures of two of them Twenty one of these I classed as true secondary renal calculi They are secondary to the following causes and associated stasis four associated with supernumerary vessels, three were metabolic, three in unrotated kidneys, two in pyonephrosis, two with tumor, two with ureteropelvic stenosis, one with ptosis, one in a horseshoe kidney, one in a case of transplanted ureter That leaves three unclassified, and they were cases of extremely advanced and destructive pathology The vast majority of intrapelvic stones are of the secondary variety, and that means secondary to something that caused urinary stasis They are strictly analogous to our vesical calculi

Of thirty six cases of stone in the ureter, sixteen could be easily classed as primary calculi, as defined in the paper The remainder defied classification, two were multiple and bilateral, nine were just low

ureteral stones, passed after cystoscopic manipulation, and one occurred in a tuberculous kidney The majority do, however, separate themselves fairly easily into primary and secondary classifications, and I omitted this evidence because I did not think it conclusive or necessary I have tried to take the simplest type of uncomplicated case and by analyzing it, to approach a possible explanation and cause It isn't possible to classify every one In other words, my effort has been to try to simplify things all the way along the line, and if (as I believe we can) we are able to show the close relationship of only the infectious origin of the primary stones and the obstructive origin of the secondary stones, we need only to grasp these two hard facts to begin to have a definite program on how to prevent, in a large percentage of cases, recurrence of renal calculi

THE MANAGEMENT OF FIBROMA OF THE RETROPHARYNX*

Report of a Case

BY HOLLIS L. ALBRIGHT, M.D.†

BENIGN tumors of the pharynx and retropharynx are rare Malignant tumors of the base of the tongue, naso- and oropharynx are far more common Because of the deep inaccessibility of benign tumors of this region, growth may continue unabated until serious encroachment upon the soft and bony structures at the base of the skull occurs, ending in the death of the patient Such a case, clinically diagnosed as a pharyngeal fibroma, was recently seen by the author‡ in which the apparently benign growth over a period of years had filled the oro- and nasopharynx, caused pressure necrosis of the antral and orbital walls, with widening of the interorbital space and ocular distortion The tumor at autopsy, however, proved to be a slowly growing adamantinoma

Steadily enlarging discrete tumors arising in the deep tissues of the neck are sometimes regarded as malignant growths, irremovable, with reliance being placed upon radiotherapy for palliation The following case report is that of a patient in whom the possibility of a malignant growth in this region was considered by Dr George H Powers of Boston who referred the patient to the Clinic for opinion and operation (Fig 1)

CASE 49450—1935—S W, a forty-nine years old white unemployed male, was admitted on July 25, 1935 complaining of a swelling of the upper right lateral neck which began seven years ago and was steadily increasing in size The tonsils had been removed in 1914 The patient was well until seven years ago when he had an abscessed lower right jaw following extraction of two teeth Swelling of the right neck in the submandibular region developed at that time and had never disappeared since To-

gether with the steady increase in size of the growth, there was progressive difficulty in swallowing plus loss of appetite and loss of fifteen pounds during the past year Speech became slurred and indis-

FIG 1

tinct, the voice became lowered in pitch and respiration audible There was increasing general weakness

Examination revealed a 119 lb lean, sallow male who showed evidence of considerable loss of weight General examination was otherwise negative There were no moles or pigmentation of the von Recklinghausen type In the upper right cervical region there was visible change in the contour of the neck due to protrusion of a rounded, smooth, firm swell-

*From the Lahey Clinic Boston Mass

† Rachenfibrom —Pathological Institute—Eppendorf Krankenhaus Hamburg Germany—January 1935

‡ Albright Hollis L—Associate Surgical Staff New England Baptist Hospital For record and address of author see "This Week's Issue" page 266

ing 8 cm in diameter. There was displacement of the larynx to the left. When the patient swallowed the tumor was seen to be pushed forcibly from its deep retropharyngeal position so as to cause markedly increased irregularity in the contour of the lateral neck. The tumor disappeared beneath the carotid vessels with displacement of the latter outward and posteriorly.

The digastric muscle was then divided at its tendinous attachment to the hyoid bone and the posterior belly was reflected superoposteriorly thereby exposing the presenting surface of the tumor. The carotid vessels were dissected free and retracted

FIG. 2.

Intra-oral examination showed marked protrusion of the tumor into the right posterior and lateral pharynx, with intact pharyngeal mucosa. It filled two thirds of the pharyngeal cavity with displacement of the uvula upwards and to the left. The tumor extended from the base of the tongue to above the soft palate and overhung the larynx with displacement of the latter to the left. (Fig. 2)

Laboratory studies were essentially negative. The bleeding and clotting times were normal. The blood Hinton was negative. A diagnosis of evidently benign retropharyngeal fibroma of probable salivary gland origin was made. (Fig. 3)

FIG. 3.

FIG. 4.

FIG. 5.

Operation—July 27 1935 by Dr. Frank H. Lahey. An oblique linear incision was made along the anterior border of the right sternomastoid muscle which was freed and retracted posteriorly. The spinal accessory nerve was preserved intact, after which the posterior belly of the digastric muscle, and the hypoglossal nerve were brought into view

laterally. The mass was well encapsulated and was delivered by digital separation of the planes of cleavage. It was necessary to divide the superior thyroid artery. The tumor was removed with its capsule intact. No attachment to nerve fibres or trunks could be made out. A gauze drain was placed

in the tumor bed and brought out through the central portion of the wound. The incision was then closed with a layer of subcutaneous sutures of plain catgut and Michel clips in the skin.

Pathologic description by Dr Shields Warren
The specimen consists of an ovoid mass of tissue, weighing 85 grams, measuring 9 x 4.5 x 4.5 cm. It is completely encapsulated and the surface is smooth. Cut section reveals a rim of yellowish gray, slightly translucent tissue from 5 to 10 mm and thick surrounding ragged cystic tissue traversed by fibrous strands, many of which contain clotted blood.

Microscopically the tumor is surrounded by a definite fibrous capsule. Peripherally, there are rows of fibroblasts with parallel orientation and marked palisading of the nuclei. Collagen is present in large amounts and is fairly dense. More centrally the tissue becomes edematous and is made up of almost acellular collagen with dilated blood vessels and some perivascular tumor cell clusters. The neoplastic fibroblasts are uniform in size, well differentiated and no mitoses are seen. There are broad regions of hemorrhage often with peripheral hemosiderin deposits. The blood vessels are thin walled. The most characteristic features of the tumor are the well-defined strands of somewhat elongated fibroblasts with prominent palisading of the nuclei. **Diagnosis:** Fibroma probably of perineural origin.

On the first postoperative day, the patient had a transient spell of acute dyspnea, choking and cyanosis which lasted fifteen minutes. However, with loosening of dressing and bringing the patient up into sitting position his condition became immediately better and his convalescence henceforth was

excellent. The drain was loosened on the third and removed on the fourth day. At the time of the patient's discharge from the hospital on the eighth day, the wound was well healed except for the small draining sinus. After the fourth day, there was noticeable improvement in the voice, with less slurring of speech, and the patient could eat a normal meal.

He was seen one month after operation. There was slight drainage from the healing sinus, which had decreased considerably in size. His condition was much improved. He had gained weight, and speech and deglutition were normal (Fig 6).

FIG 6

At the end of two months (September 20, 1935) he had gained twenty seven pounds, felt well and was restored to his normal activities.

IONIZATION IN THE TREATMENT OF HAY FEVER AND ALLIED CONDITIONS*

BY SAMUEL W. GARFIN, M.D.,† AND SAMUEL M. PEARL, M.D.†

INTRODUCTION

THE use of the galvanic current in the treatment of various nasal affections has been known to medicine for many years. St. Clair Thomson¹ mentions this as a means of treating "nasal hydnorhea," the source of his information being an article published by Creswell Babel in 1898.

Ionization, using zinc solutions, has also been widely employed in various affections of the nasal cavities. Norris² has employed this method of treatment for the reduction of large inferior turbinates and reports good results with it. Fox³ used it in the postoperative treatment of maxillary sinusitis and Hollender and Cottle⁴ for chronic rhinitis. Harris⁵, Feldman⁶, Gale⁷, McCoy⁸, Sputh⁹ and many others have employed zinc ionization in many rhinologic conditions and report successful results.

Intranasal zinc ionization for the treatment of hay fever and its allied conditions is of more recent date. Hollender¹⁰ has administered more

than 1000 ionization treatments during the past ten years for various rhinologic conditions and more recently has utilized this method extensively for seasonal and perennial hay fever. Démétrades¹¹ and Franklin¹² report favorable results in the treatment of vasomotor and hay fever conditions. Of more recent date, encouraging results are reported by Warwick¹³, Alden¹⁴, Hays¹⁵, Haseltine¹⁶, Tobey¹⁷ and others.

Ionization

There are three principal actions of electricity on conductors, mainly, chemical, thermal and electromagnetic. Chemical action is mainly produced by direct currents. When a galvanic (direct) current is applied to an electrolytic solution, this latter is split or dissociated into its component atoms, and negative and positive ions are liberated. This chemical process of dissociation is known as ionization¹⁸. The transmission of these chemical ions into the tissues by means of an electric current is known as "Phoresis." The process is really Iontophoresis and not Ionization.

Historical

Iontophoresis or Ionization was first introduced about the beginning of the century and

*From the Department of Immunology and the Department of Laryngology of the Boston City Hospital.

†Garfin, Samuel W.—Assistant Surgeon Aural Service Boston City Hospital. Pearl, Samuel M.—Physician for Immunology Boston City Hospital. For records and addresses of authors see This Week's Issue page 266.

at that time had many enthusiastic followers Leduc¹⁹, the chief originator of ionic medication, maintained that its chief advantage was that it enabled the introduction of drugs in any quantity and at the exact point required. He proved by classical experiments that the effect was actually due to the flow of current and not to simple absorption by the skin from the wet pad soaked in the drug. A pad of gauze moistened with a solution of strychnine sulphate was applied to the internal surface of a rabbit's ear and held down by a small metal plate. Even if the pad was thus left in contact for a long time, nothing happened. If however, the pad was made part of a galvanic circuit and connected to the positive pole while an indifferent pad electrode moistened with water or salt solution placed against any other part of the rabbit's body was connected to the negative pole, upon starting the current flow in a few minutes the rabbit was seized with convulsions and died with the symptoms of strychnine poisoning.

More recent investigations have also established that the moment a medicinal ion enters the body, it is almost immediately deprived of its charge by the electrolyte of the body fluids, the blood stream and lymph. Everything points to the fact that ions from the outside cannot be introduced into any but the most superficial tissues, and beneficial results in lesions of deep structures when ionic medication is employed are simply due to the passage of the galvanic current itself and not to any medicinal solution in which the electrodes are soaked.

Method of Procedure

The treatment consists in thoroughly anesthetizing the entire nasal cavity, following this the nasal chambers are again packed with cotton strips saturated with a metallic solution. This consists of one per cent zinc tin and cadmium chloride in glycerine. A bare copper wire varying in gauge from 12-18 is placed in the packing in such a manner as to avoid direct contact with the nasal mucosa. This acts as the anode or positive pole and both sides of the nose are treated simultaneously. The cathode or negative contact consists of a pad soaked in saline solution and brought in contact with the patient's palm. The galvanic current is gradually turned on until the ammeter registers about 10 milliamperes and the treatment is continued for about fifteen minutes. In our experience the average was 12 ma for twelve minutes giving about 150 milliamperes minutes. However, no hard and fast rule can be applied as the amount of dosage in each case as this is a matter of experience which is acquired by practice. It is important to bear in mind that excessive current and prolonged time period may result in coagulation of the tissues which must be avoided.

The discomfort during the treatment is

slight. There is profuse salivation the patient experiences a metallic taste and at times feels a tingling sensation in the nose and about the upper incisor teeth and roof of the mouth.

The Reaction

When the packs are removed the nasal mucosa is covered with a greyish film which cannot be removed by rubbing. The reaction begins within a few hours following the treatment and reaches its height within eight hours. The turbinates and the other parts of the nasal mucosa become swollen and breathing becomes impaired. The patient complains of nasal obstruction of varying amounts of pain about the nose and face with headache. The reaction varies in different individuals and is in proportion to the intensity of the treatment. On the second day following the treatment the pain subsides the nose, however, is still obstructed. Most of the patients are now able to resume their usual occupations. At this time, too, a gelatinous membrane forms within the nose about the turbinates, the septum and floor of the nose. Thus the patient is able to expel on the third day following the treatment. In some cases this was removed in order to facilitate nasal breathing. By the end of the third or fourth day the nose is usually free of membrane, the turbinates have decreased in size and the mucosa generally appears moderately reddened, with slight crusting. In most cases, as will be detailed below, the patient is relieved of his symptoms. At the end of six days rhinoscopy reveals a comparatively normal appearance of the nose.

The theory of this treatment is that when a metallic solution is brought in contact with the nasal mucous membrane precipitation of the proteins of the superficial cells takes place but when a mild current is passed through the tissues the metallic ions penetrate more deeply and precipitate more of the proteins of the cells.

It is our opinion that this change which takes place in the nasal mucous membrane as a result of the reaction to ionization, renders the nasal mucosa less sensitive to external causative agents whatever they may be. Following the theory of Coca²⁰ that the nose (nasal mucous membrane) being the shock organ which initiates the attacks the treatment alters the nasal mucosa in such a way as to make it "shock proof."

The total number of patients treated was sixty-eight who received about 100 ionization treatments and included the following:

1	Vasomotor rhinitis	25
(a)	" with hay fever	5
(b)	" " asthma	5
2	Hay fever	
(a)	Early (spring)	7
(b)	Late (summer)	6
(c)	Early and late	2
3	Hay fever with asthma	13
4	Asthma	"
(a)	Pollen	5
(b)	Bronchial	2

Before treatment was begun, the patients were examined in the department of allergy either by Dr Sanborn or Dr Pearl and treatment of these patients was undertaken after consultation with the department of allergy. In many cases, especially those which did not respond to the immunization or who presented themselves too late for injections, ionization was undertaken at the request of Dr Sanborn or Dr Pearl.

Among the patients with vasomotor rhinitis, there were a number who had various degrees of infection, one, Case 44, had a pansinusitis of extreme degree. One patient, Case 17, had bronchial asthma and another, Case 7, gave positive tests to animal emanations. (See table.)

In a number of patients the clinical findings were at variance with the symptoms. The patient would complain bitterly of severe sneezing attacks, obstructed nose and copious watery discharge, yet clinical examination very often failed to show the typical vasomotor appearance one would expect. Treatment in a number of these cases was undertaken very reluctantly and it is most gratifying to report that the greater number of these patients were entirely relieved of their symptoms.

Results of Treatment

There were thirty-five cases of vasomotor rhinitis, five of which suffered in addition from late hay fever, five from asthma, and one from tree pollen fever. A number of the vasomotor patients also had purulent rhinitis, but the sinuses were negative by Roentgen examination. Of the straight vasomotor cases, all but two, Cases 2 and 45, were entirely relieved of their symptoms. The majority received only one treatment. Those who were not relieved received two comparatively intensive treatments. The most striking results were obtained in Cases 3, 23, 27, 37 and 48. Case 3 is a boy of ten years with extreme vasomotor symptoms in addition to a marked purulent rhinitis. He was referred to the hospital by a very competent rhinologist with a diagnosis of chronic bilateral ethmoiditis and an operation was requested. The x-ray of the sinuses did not show sinusitis. He was treated for three years with vaccines and pollens with very little relief, and at the suggestion of Dr Pearl, received one ionization treatment. The patient went through the usual reaction and, when he returned one week later, was entirely free of symptoms and rhinoscopy showed a normal appearance of the nose. To date of writing, three and a half months since the ionization, the patient is entirely free of symptoms and shows marked improvement in general health.

Of the five patients who had vasomotor rhinitis and hay fever, four were entirely relieved, one obtained about fifty per cent relief. These

patients were treated at the time their hay fever symptoms were most active.

Of the four patients with vasomotor rhinitis and asthma, all were relieved of their nasal symptoms. In two of these, Cases 17 and 63, the asthma has been markedly improved the time elapsed since treatment being three and four and a half months respectively. In one patient, Case 44, an extremely severe case of vasomotor rhinitis, asthma and pansinusitis, a marked improvement was obtained in the nasal symptoms and the asthma. One patient, Case 43, is entirely free of both vasomotor and asthma symptoms, but only a short time has elapsed since the ionization and it is, therefore, too early to evaluate these cases.

All the early hay fever patients were treated during the active stage and received one treatment. They were all completely relieved of their symptoms and remained symptom free during the season. The late hay fever patients uncomplicated by asthma, were also entirely relieved by one treatment. One patient, Case 55, obtained fifty per cent relief. There were thirteen patients who in addition to hay fever had asthma. All of these patients were relieved of their hay fever symptoms and in most instances obtained partial or complete relief from the asthma. Case 18 was completely relieved of hay fever, but the asthma was not materially influenced.

The relief of symptoms in asthma, in the majority of patients, began in seven to ten days following treatment. In some patients, however, the asthma was relieved as promptly as were the hay fever symptoms.

There were seven patients with asthma not complicated by hay fever. Two of these were not relieved at all, two (with pollen asthma) were markedly relieved and became almost free of symptoms. To date of writing, however, only a month has elapsed since treatment, two patients with bronchial asthma remain entirely free of symptoms to date, about one month following treatment.

It is our opinion that the best results can be obtained only by the cooperation of the allergist and rhinologist. An effort should be made by the allergist to establish the cause of the patient's condition and eliminate it if possible.

CONCLUSIONS

- 1 This is a preliminary report of six months' experience in the treatment by ionization of sixty-eight cases of hay fever (100 ionization treatments), vasomotor rhinitis and asthma.
- 2 The immediate and complete relief from symptoms is most remarkable in vasomotor rhinitis and hay fever treated during the active stage of the disease. Only two patients out of thirty-five vasomotor cases failed to obtain immediate relief.

- 3 In twenty asthma patients both with and without hay fever or vasomotor rhinitis, no relief was obtained in two, eighteen were relieved from 50 to 100 per cent. The asthma patients with nasal symptoms were practically entirely relieved of their nasal symptoms.
- 4 The change in the turbinate and the rest of the nasal mucosa to a healthy appearance within a period of four to six days is in most striking contrast to the previous sickly pale boggy, edematous and waterlogged condition.
- 5 No ill effects have been observed in any of the cases.
- 6 This being a preliminary report, the permanency of this relief cannot as yet be evaluated.

We wish to express our sincere gratitude to Dr. George P. Sanborn the chief of the department of laryngology and to Dr. Louis M. Freedman chief of the oral service at the Boston City Hospital for their many helpful suggestions in the preparation of this work.

MASSACHUSETTS MEDICO-LEGAL SOCIETY

WHY PEOPLE COMMIT CRIME AND HOW
TO MEET THE PROBLEM*

BY AMOS OSBORNE SQUIRE, M.D.†

Dr. Gay and Members of the Profession

MINE is not a paper. It is not very scientific. According to your program I was asked to speak on "Why People Commit Crime and How to Meet the Problem."

Sometimes, I wonder why I should be invited to speak on crime by the profession. I remember some years ago discussing this subject before the Medical Jurisprudence Society of New York and the Manhattan Medical Society. At the conclusion of what I had to say, a doctor came to me and complimented me on my address and said, "I hope that I shall never meet you up the River." I said I hoped I wouldn't meet him. Some two or three years later, I was examining the new men at Sing Sing, and as I was examining one of them this chap said to me "Do you remember me Doctor?" I said "No I do not." He said "Do you remember speaking before the Academy of Medicine in New York and somebody came up to speak to you and said 'I hope that I shall

never meet you up the River?" I said, "I think that did happen." And he said, "I am the doctor who made that remark."

The only thing I can say to you is that I think you are on thin ice, but of course that doesn't apply to Dr. Gay.

I have been Medical Examiner of Westchester County for ten years, and have been connected with Sing Sing Prison since 1900. I am now Consultant at Sing Sing. But, during those years, I came in contact with and examined probably some 30,000 inmates. Taking a history of these men, naturally I made some observations on the criminal situation and I know that there is no group of people to whom I would rather talk more than I would to a group of medico-legal minds.

We should be interested in crime first because it is costing so much money. I don't know whether you read Senator Copeland's statement, when he was Chairman of the Crime Commission of the Senate, but during the investigation it was brought out that crime is costing \$13,000,000,000 a year in the United States. It is rather difficult for us, as medical men to conceive of what a billion dollars is but I have

*Read at the meeting of the Massachusetts Medico-Legal Society, February 9, 1928.

†Dr. Amos O. Squire, Chief Medical Examiner, Westchester County, New York. For recent articles see "This Week's Issue," page 166.

been told that a billion dollars would be the result of counting a dollar every second from the time a man is born until he got to be thirty-three years of age

We, as medical men, are interested in crime, then, because we are paying for it

We are also interested in it because so many people commit crime. Today, we have approximately 117,000 prisoners and 200,000 in our reformatories. William J. Burns, just prior to his death, told me that he presumed, after making a study, that not over ten per cent of the people who commit crime are ever apprehended or punished.

We have a large group of antisocial people in our country. I have thought for some years past that the reason there is more crime than ever before is due to the fact that there is too much disrespect for the law and disrespect for the lawmakers, because, as a country, we are a great manufacturer of laws. We have, in this country, over two million laws and ordinances. We manufacture them at the rate of one hundred thousand a year. Almost everybody who is selected by the City Government or the State or the County or the Federal Legislature thinks that his reputation is dependent upon the number of laws suggested during his tenure of office. I remember attending a prison conference where one thousand penologists were present from all over North America for a week. A State Senator spoke at the meeting. He said that he had been a Senator for ten years and that he had one plank in his platform, to vote against every law suggested, and he expected to remain a Senator as long as he lived. When he got through, I went over and shook his hand, and, by the way, he was from Massachusetts and said, "Old Man, if I ever move over into Massachusetts, I will move into your district."

The reason there is disrespect for the law is because laws have been enacted that are never intended to be enforced, or else we have had antiquated laws to which nobody pays any attention.

I went down to Pinehurst last spring with my family. On the way down, we thought we would go to Virginia Beach, so we had to go to Norfolk and we decided to stay there all night. On the way through the city, I was stopped twice by two different policemen, telling me that I had broken the traffic ordinances of Norfolk. I apologized, saying that I was trying to obey, but explaining that the laws that I had disobeyed were not in vogue where I came from. After dinner at the hotel, I sat in the lounge, alongside of a gentleman and we engaged in conversation. I said to him, "Where do you live?" He said, "In Norfolk." I said, "You have an interesting city, a fine city. But you know, coming to this hotel tonight, I was stopped twice by the officers, telling me that I had broken ordinances." He laughed and said,

"Don't worry. We have one hundred and sixty-seven ordinances for crossing the street."

And so it is that we have in this country of ours more laws than the combined laws of any five countries of Europe. The late Chief Justice Taft of the Supreme Court, and also the present Chief Justice Hughes, have repeatedly stated before Bar Associations, in discussing the criminal situation with the lawyers, that the great number of laws is one of the reasons why we have so much crime, because we have developed a disrespect for law.

I have never agreed with the Lombroso theme that those who commit crime appear different from the rest of us. In other words, after thirty-five years' experience, I never felt as though I could go down Broadway and pick out a criminal. They look and talk just as you and I do. Lombroso stated that people who committed crime, particularly the psychopathic, had receding foreheads, big ears, high cheek bones, coarse, dark hair, and sometimes the murderers had a twitching of their mouths to one side.

I have felt for sometime past that probably the increase in crime, and one of the causes of crime, has been the moving picture. I have been impressed for years that the showing on the screen of the taking of human life and showing homicide to be of no particular value, cannot help but impress some children, particularly, that life is not so valuable as you and I hold it to be. This was brought out particularly at the murder trial of two-gun Crowley at which I testified recently. This poor boy, with another boy, had committed murder of a girl by the name of Brennan, who came from a Maine city and who was tired of the quiet of her town and wanted to go where there was more life. She landed in New York in a speak-easy and hired herself out as a hostess, in one of those places where you pay ten cents for the purpose of dancing with some person you have never seen before. Coming up from New York one night, Crowley was driving the car and Dirwinger was in the back seat, apparently without any reason, Dirwinger killed the girl in the back seat. They didn't know what to do with the body until they come to my county, and there they threw the body over the wall in Yonkers. I was notified and performed an autopsy on the deceased. And, of course, it is assumed that a crime is committed where the deceased is found. Later, it was discovered that the crime was committed in the Bronx, so we tried him in the Bronx. But the point I want to make is this. I was subpoenaed and appeared at the trial because I had autopsied the deceased. I was waiting to be called, and before I was called, there was a recess of five minutes. I walked a little fifteen-year old high school boy. On one side of him was his counsel, appointed by the Court. They were coming up before the Bar to discuss with

the Supremo Court Justice whether this fifteen year old boy was to be tried in the Supreme Court or in the Children's Court, because of his age. We have a law in New York State, particularly applying outside of New York City where delinquents under sixteen should be tried in the Children's Court. The Judge, looking down on this little boy, said to him, "How is it, son that you could have been accused of a crime at your age?" And the little lad promptly said "Your Honor, I saw it in the movies." This little lad, with another group, had gone to a delicatessen store and had held up the man in his place of business. I can picture the delicatessen man seeing a group of children, playing with them, failing to hold up his hands, and this little boy shooting him.

I am a firm believer that moving picture producers and managers of moving picture houses owe a duty to society to produce clean, whole some moving pictures.

I remember the night we were to electrocute the Diamond brothers and one other. I felt kindly toward one of the Diamond brothers, the younger of the two. It so distressed me that I took a walk up Broadway, and thought I would go to a moving picture in order to divert my mind before the duty which I had to perform later in the evening. Finally, I did go to a moving picture house, and in the first thirty minutes, they killed seven on the screen just the thing I was trying to avoid. It so annoyed me that I had to get up and go out and wait around until it was time to take the train back to the prison.

I am a firm believer that the motion pictures have played a big part in our present criminal situation.

Of course, there is no doubt in the minds of those who have studied the criminal situation that environment is probably the greatest single agency which produces it. Those of us who come from large cities, like Boston and New York, realize that there are certain situations and there are certain sections of our cities where children are playing on the highways and the streets. I remember attending a conference with Warden Lawes and Father Cashman. We went down in the lower east side of New York, and we saw thousands of boys and girls playing games of chance, using profane language. Father Cashman turned to me and said, "Isn't it strange that we don't have more criminals when we realize their environment?"

Some years ago, I used to receive letters from mothers all over the country, wondering what the prospects were of their little boys becoming criminals because they were left handed. They had read this in a magazine somewhere, probably. One woman wrote me that she was very much perturbed about her six year old boy, who was left handed. I was glad to answer

letters like that, because I could reply and tell them that the person answering the letter was left handed, and so were my father and my brother, and, although I had been in prison for twenty five to thirty years, I had been there through choice. I went down to the Library in New York about this, and I wasn't able to find anything on it either there or at the Academy of Medicine. And so I began to gather statistics. Out of the next five thousand men who came to Sing Sing, I found that ninety six per cent were right handed and the balance left-handed, which would probably be the percent age you would have of the group here.

We have been very much depressed over the increase in drug addicts as a source of our crime situation. Prior to 1919, and that is rather strange because prohibition was to go into effect that year, but I can't find any connection between that and drug addiction, for a period of six years, our average admission to Sing Sing Prison, as far as the drug problem was concerned, was thirteen a year. So when I tell you that thirteen out of fifteen hundred new men coming to us in one year were drug addicts, you will say that that isn't much of a problem. In 1917, there were four. In 1920 the number had increased one hundred per cent. In 1921 it had increased five hundred per cent over the average. In 1922, it increased nine hundred per cent. Now as a country we used more dope per 100,000 than any other country in the world. We exceeded China.

I appeared before the Foreign Relations Committee in Congress on a resolution presented and signed by the President, asking the foreign countries to grow fewer poppies, in the hopes that there would be less drug addicts in this country. It is presumed that there are approximately 2,000 tons of opium produced in the world each year. We are reliably informed that the scientific and medicinal needs do not exceed seventy five tons. So we have the difference between these amounts, which difference has a relation to the problem of those people. Congressman Porter went to Geneva and sat in with the League of Nations Division, trying to persuade Great Britain, Serbia, Turkey and other countries to raise fewer poppies. After remaining five months, he reported back to the President that these countries refused to grow less because they were receiving a revenue from its growth and sale. The next year, I was privileged to appear before Congress on a bill passed to forbid the importation of opium for the purpose of making heroin. You know you haven't been able to procure any legally in the last ten years. But, I am sorry to report that there is probably as much dope smuggled into the country, and I am particularly speaking of heroin, as there is here, or was here legitimately and prior to the enactment of that law.

I am particularly interested in heroin because of the crime situation. Ninety-six per cent of the addicts are heroin addicts. It is a drug of youth, convenient to take, either by snuffing it, by mouth or by hypodermic injection. A study of the men who come to us has convinced us that a great many of the murders, with no rhyme or reason for the commission of the crime, and robberies, never would have been committed if it had not been that the persons had been doped with heroin. Take the Becker murder case, those four gunmen, prior to their deaths, stated that each of them in the pool room, had doped himself with heroin before he went out on the street, for the purpose of killing a man he had never seen before.

I am deeply concerned about how we are going to counteract this habit with our youth, particularly our boys. We know that these bootleggers of heroin sometimes will hang around high schools and give boys, particularly, a little snuff of this drug, in order to create a group that they might sell the drug to, and then carry on their terrible design.

I have never been impressed that the war, as a cause, had very much to do with the increase in crime. The average age of the prisoner today, according to the government's statistics, in the whole United States, is twenty-three years. Forty per cent of all crime committed in the United States last year, and that means that those who were apprehended because of crimes, were in their nineteenth year. There were more in their nineteenth year than in any other age group. Now, the war has been over for the last sixteen years. Therefore, the average prisoner today in the United States was under five years old when the war was over. He certainly never was overseas. We thought that maybe the crime increase after the war was probably due to the men who had been overseas, because of shooting people there, so that when they came back to the States they forgot the war was over and continued shooting people. So, having been in the service during the war, I was rather anxious to gather statistics. We asked every man whether he was or was not in the service. I remember one year, out of seventeen hundred new men, I found only fifty-two had been in the army or navy, and only twenty-six of them had been overseas, which is, of course, too small a percentage to blame the war, for the cause of the present crime situation.

Then, again, it is said that some people commit crime because they are not very well developed mentally. During the World War, I was in the Navy. I examined many hundreds of men for the service. Then, for a while, I examined the men in the draft. I was impressed with the fact that the men I was examining for the service were no higher mentally than the men in prison. When the War

was over, I wrote to the Secretary of War at Washington, and asked him to give me an idea of the mental level of the group that went to War from the states. He replied that two and a half million men from the states were presumed to have a mental intelligence of fourteen or fifteen years. The white men in the draft, because they were psychologically examined, had an intelligence of thirteen years and six months. And twenty thousand colored men had an intelligence of ten years and three months.

All that was within two months of the mental level of the men we had in prison.

Another group of people who commit crime are designated in penology as psychopaths. They make up about thirty per cent of our prison population. Generally, they are college graduates, or high school graduates, certainly a large group of them have sufficient schooling to insure good behavior. In order for me to convey what I want to, let me tell you a story.

Some years ago, I had, as one of the inmates in prison, a young chap who happened to have graduated from my college. His brother is today, and has been for years, one of our most successful physicians in New York City. I knew his mother, because she used to come to see her son in prison. Soon after he was graduated from college, he committed a crime in New York and was sent to Elmira. He came out of there and then was sent to Sing Sing for ten years, and then, after his discharge, came back for five years. It was during this five-year period that I was looking for a secretary, and I selected him. He kept saying to me, "Doc, I don't mind doing the five years here because I am very definitely guilty, but I hate to think about the ten years sentence that I served, because I wasn't the chap in that woman's apartment." Well, he kept telling me that right along, and I got rather tired of listening to it. So I said to him, "Let's write to the Court and find out if the stenographer still is alive, and if he has the minutes of your trial, I will purchase them, and if I think there is any doubt of your conviction, I will ask the Governor to commute you."

Well, the court stenographer was still alive, so I purchased the minutes and read them over. I interviewed his brother, who was a doctor, and I said, "Was Frank in her apartment?" He said, "Doctor, there may have been a mistake in that case. I wouldn't say. But I happened to have been in the house when the cops came after that burglar raid, and they brought out but one picture, and that was this fellow's picture, and they said, 'Does that look like the chap in your apartment?' And she said, 'It does.'" So that led me to think there was some doubt. But, in the meantime, Frank had become re-

higious. He used to go to church every Sunday. He also used to publish the prison bulletin, a very excellent magazine, where the contributions were given by the convicts. Each issue contained two or three pieces of poetry that Frank composed.

So, having all these data, and considering the fact that he had reached thirty-seven years of age, I thought maybe he had reached the point in life where, if he were given one more chance, he would go straight. So I went up to Albany paid my own expenses, interviewed the Governor, and told him the story. He said, "Well Doctor, you should be able to pick one out of twenty or twenty-five thousand to go straight. I will take a chance." I said, "Governor, he is the best medical stenographer I ever had. I can procure a position at \$50.00 a week for him with a Doctor." In the meantime, I, of course, got in touch with my doctor friend, and had this chap paroled. He was engaged by my doctor friend.

I went to lunch with Frank about once a week because I wanted Frank to go straight. I wanted him to go straight because of himself, and secondly, I didn't want the Governor to twist me the rest of my life over the fact that I couldn't select somebody who might go straight. After going to town for six or seven weeks to have lunch with him, I called my doctor friend one day, only to find that he hadn't showed up there. Then, I began to get disturbed. Two months later, I was walking into the prison and the guard said, "The Warden would like to see you." So I went down to Warden Lawes' office, and he showed me three checks, totaling \$1,300 that Frank had stolen from the prison. He had gone to work, when he held the position in New York and he had sent three bills to Sing Sing Prison for coal presumed to have been delivered at the institution, and Frank, with the crooks inside, had approved the bill, and forged the signatures of heads of departments. Well, the checks had gone across the hall to the Warden's office, and the Warden had signed on the dotted line. Frank had intercepted the checks and cashed them in New Jersey. They sent Frank's finger prints all over the country, and within two months, word came from Pittsburgh that a fellow with finger prints exactly like his was being detained. And so there was Frank, this college graduate, indicted on fourteen counts in Pittsburgh, they gave him ten years there.

I had to go down to Pittsburgh on some business later, and I thought I would go down and see Frank and incidentally the Warden whom I knew. I was hoping that Frank would say to me, "Doc, I am sorry. I am sorry that you spent \$150 to procure the minutes of my trial and that you went to see the Governor." But

when he was sent for, all he said was, "Doc, how's the gang?" He was absolutely unmindful of what had been done for him.

Well time went on, and I think it was in 1925 that I had been appointed Medical Examiner in Westchester County. He saw in the Pittsburgh paper, mention of the fact that I had a suite of offices with the District Attorney at the Court office in White Plains. Well, I could picture him saying, "Doc must be pretty close to the District Attorney. Maybe he could get this warrant squashed." So he wrote me.

"Dear Doctor

"You must be close to the District Attorney. Won't you please use your influence to get that squashed for me? If you do, I will save about three years down here."

Of course, I wrote to Frank and told him that I thought I had gone as far as I should.

Time went on, and he served his time, and he came back to Sing Sing for the unexpired time that I had got him out of. Well, last February, he left us. And the day before election last fall I was back in Pittsburgh and I thought I would go down to see Stanley Ash, the Warden of the Penitentiary there, after I had spoken before the Rotary Club. I said, "Stanley, the last time I was at this Penitentiary, you had an old friend of mine here." He said, "What was his name?" I told him and he said, "My God, he is here now!" Well, the Warden sent for him, and the first thing the fellow said was, "Doc, do you know I think I will die in prison!" I said, "Frank, I know you will."

He is a psychopathic criminal, and nobody but God himself can rehabilitate a man of that type.

Then we had another case. Some years ago, you people heard a lot about the Mutual Welfare League, an organization for the purpose of having self government in prison. The newspapers played it up. The moving picture people took pictures of us. We had a convict Court, they were voted on and believe me they are always ringleaders, and they are a fine bunch to sit in Court on some of their other inmates! Coming into the prison one day, there was a well-dressed man leaving. I overheard him saying, "You know this whole thing meets with my favor. I think it is a wonderful scheme, this Mutual Welfare League. I would like to donate something to its cause." So he pulled out a check and wrote it out for \$100 and gave it to the person with whom he was talking. He went a few feet, turned back and said, "By the way [after fishing for his wallet], I must have left my wallet on the dresser at home. Won't somebody cash a check for \$10 for me?" So somebody handed him a \$10 bill. He went out. Four days

elapsed and both checks came back, "No account in the bank"

Those of us who knew the incident realized that it wouldn't be long before the man would be back in Sing Sing Prison. Six months later, I was examining the men, and as I looked down, I thought I saw the profile of the person that I had seen six months before out in front of the prison. When he came up to me, I said, "Aren't you the fellow who gave the phony checks?" He admitted that he was.

Now, he was a college man and one of the cleverest forgers I have ever known in prison. Most of the forgers in prison trace. But this chap, we will call him Mike because that isn't his name, could take a piece of paper with your name written on it, give him just ten seconds to look at it and he could take a similar piece of paper and write your name and you could not tell which was which. He was most unusual. When my friends visited me socially, I would pull in Mike and I would show how he could forge a signature without doing a bit of tracing, and with only a ten seconds' observation. We never would present a set of resolutions unless they were penned by him. He had been in prisons all over the world.

One day he had a magazine in his hand and I could see a picture as he opened it. He wanted me to read it, and I said, "With your consent, I will take it to the hospital with me and read it." It was the *Bankers' News*, a magazine published by the banking group, and in it was an article by William J. Burns, chasing this man from Portland, Maine, to Portland, Oregon, and from Quebec to Cuba. Later when I saw him, I said to him, "My gracious, Mike, but you have an awful record." And he said, "Doc, it isn't half there."

There is another case of a college graduate.

Now, I don't know about you ladies, but we men, when traveling much, generally talk to whoever may be in the train. I remember, when I was going to a prison conference in New Orleans, we went by way of Chicago. I got on the train at the Illinois Station there, and went into the smoking end before I retired. I was alone for a moment, and presently a well-dressed man came in. I offered him a cigar and we smoked. He said, "Where do you hail from?" I said, "Sing Sing Prison." He looked me over rather carefully, and we discussed Sing Sing. "Where do you hail from?" I asked him. He said, "Walla Walla Prison." Having been there, we discussed that. I said to him, "What are you there?" He said, "I happen to be the Warden." I discovered that we were going down to the same conference, and the first thing he said to me, after we became acquainted, was, "Did you ever have Mike?" I said, "Yes, we have had him three times."

And I say again, he was a college graduate, a very shrewd man, who, in ordinary times,

probably could command \$1,000 a month for his ability, but still a chap who lived the life of a psychopathic criminal.

That is the reason why some of us interested in penology have come to the conclusion, and I am talking particularly about New York, that when you sentence a man to prison, there should be a minimum and no maximum. In other words, in the case of every person who goes out on parole from prison in New York State, the Parole Board gets the opinion of the Chaplain and the Warden, as to what they think of the prospects, but where you have a person who has a definite sentence, it doesn't make any difference what you think, his time has expired and he goes out. And, with psychopathic criminals, who make up thirty per cent of our population, you can readily understand what a tremendous tax it is on the people to support them.

It costs New York \$2,000 of the taxpayers' money to send a man to Sing Sing. Probably the time will come when we will not have any maximum sentence. But, the psychopathic criminal will be with us until he reaches his last days.

Now, what about capital punishment? Massachusetts, I think, has it. I used to feel, personally, that maybe capital punishment was best. But, when I tell you that last year, in this country, we had 12,000 murders, and only 112 people executed because of them you can readily understand what a small percentage suffer the extreme penalty.

As a Medical Examiner, and having a murder once a week, I see the fallacy of capital punishment in our State, as carried out today. In other words, I believe that if we are to retain it in order to lessen crime, we should apprehend, indict, try and carry it out in a short space of time. I can tell you that I have caused to be electrocuted condemned men who have waited in their cells for three and one-half years. I said to Warden Lawes about one of them, "He will die from natural causes before he gets to the chair."

I say that if we are going to retain capital punishment, let us have it like one, two, three, and it's done, and not the way it is carried out today here. I really don't think that people mind dying in the chair now. I have known two hundred men condemned to death, and I have given the signal for one hundred and thirty-eight of them, and I have never yet seen anybody give a hang, going to the chair. Certainly, we never have to stimulate them. I never had anybody ask for a stimulant, except one man. That was years ago, and I received an emergency call at three o'clock in the morning, being informed that the man in the pre-execution cell was in danger of losing all control of himself. I mixed a dose of aromatic spirits of ammonia, the stimulant for such an

instance, and hurried to the man's cell. He and the Chaplain, both alarmingly pale, were sitting on the cot, side by side. Except for the difference in dress, it would have been difficult to tell which was facing death. When I held out the cup containing the ammonia, the condemned man waved it aside and said, "Give it to the Chaplain, he needs it more than I do."

We had another case of a fellow by the name of Becker. As I was going through the condemned cells, this fellow said to me, "Doc, I am doomed to die on Thursday, and I don't want to die on Thursday." I said, "What is the matter with Thursday?" He said, "Thursday is my boy's birthday, and I don't like to have him think that his father died in the electric chair on his birthday." Well, I went down to Warden Lawes' office, and said "Did you know that Thursday is the birthday of Becker's boy?" He doesn't care whether we kill him tomorrow or Friday or any other time but not on Thursday." Well, we kept him alive until Saturday.

You know, I was interested in your statistics here. I have had, as Medical Examiner in the last ten years, over six hundred and fifty cases, where I have officially declared them to be suicides. I have had about four hundred more where I have had to say they were accidents or homicides. I suppose the law is similar to that here in Massachusetts. The law presumes that a man doesn't take his own life. And as I say, I have to sign a lot of these and in the back of my head I am satisfied that they are suicides, but I have to classify them as homicides or accidents, and not suicides.

I think I don't know of a man who has been in a condemned cell who wouldn't rather go to the chair than to isolated sections of our State away from the group and without any hope of ever being pardoned with writing privileges and visiting privileges denied to him. To my mind he would be dead as far as society is concerned. I would put him in a place like that in the State and make him work.

Why we had three suicides in the condemned cells because they got tired of waiting. One of them was a fellow by the name of Flood. He was the only chap in the condemned cells for execution who came under that particular law in New York which says that if you set fire to a building intentionally and anybody is killed in that building it is murder in the first degree. Flood was the only chap who ever came to us for that particular crime. He was man of unusual intelligence, and he made a thorough study of the death house routine and discovered a flaw that no one else had detected. After perfecting his plans, he wrote a letter to the Warden, saying that he hoped the guard would not be blamed, or suffer discipline or dismissal, since in what he was about to do the guard was in

no way at fault. He had found that the only time when he was not under direct observation was when the guard on duty was collecting spoons and plates. Except when engaged in that duty, the guard sat where he could see the occupants of each cell in the wing. Flood's cell was at the end of the corridor. The guard came for his spoon and plate first. Flood timed him and learned that it took an average of four minutes to complete the rounds after a meal. On the basis of that knowledge, he worked out a way to destroy himself. On the wall opposite the row of cells, was a clock, which was visible from the end cell occupied by Flood, but not from all the others. Just after dinner one night, an inmate who could not see the clock called to Flood to ask the time. Flood did not answer. The call was repeated longer and until Flood did not answer. "He's asleep," said the guard, giving the other inmate the time. "He dropped off to sleep mighty quick." "Yeah." The guard stared at Flood who lay on his bunk, face to the wall, "Must be sleeping pretty sound." After a moment, the guard became suspicious. He got up and went over to investigate. Flood was already dead. He had arranged a towel around his neck in such a way that it was hidden beneath his shirt collar, and facing the wall, he had twisted it, strangling himself. While gathering up the utensils, the guard had never been more than fifteen feet away, but Flood had carried out his plan with such swiftness, deftness, strength and determination that he died without making a sound that could be overheard.

So I say that if we had some distant part of the State that could be taken out of politics and put into the hands of the Court of Appeals where these fellows could be made to work, it would be much better. Deny them visiting privileges and writing privileges let them be legally dead. To my mind that would be a much more severe penalty than the death penalty.

Now, what are we going to do to meet the problem? The first thing that suggests itself to me is to deport the alien criminals.

There was a murder in Ossining a few weeks ago. A girl was stabbed to death. I sent the body over to the morgue and took everybody out of the house and sent them up to the Police Station. In Westchester County, the Medical Examiner does the investigating, he is the one who holds the hearing on the matter. After I had autopsied the victim I went up to talk to these people. Later, we found that this woman who was stabbed to death and all these people in jail were smuggled into the country through New Bedford. They admitted that they gave the fellow who ran the ship \$50 apiece to forget that they had come over. Knowing that I couldn't pin the murder on a particular one of

them, I said that I would get rid of all of them. So I called up the Immigration Officer and told him to come over and get them. But the Police Chief finally said that he was sorry to report that he couldn't send any of those people back, because they were smuggled in before 1921. Probably Ossining is supporting them as the "unemployed" now.

The other day, we had a case in Rye, New York. There was a fellow there who admitted to me that he was illegally in this country from Germany. He had hired himself in Hamburg as a waiter, got over to Hoboken and left his ship, staying here a couple of years illegally. He went back to Hamburg and spent a year, and then he came back to the States in 1913. Then the War was on so he thought he would go back to fight for Germany for a couple of years. So he spent three years in the German Army. But the United States is a good place to come back to, in his estimation, so he came back as a waiter again. When he got here, he bought a lot of canned fish in cheap places, and he peddled this around in the residential section of Westchester County. Well, he sold a can of fish to one of the residents, who died in two hours, and more of them nearly died. I couldn't get him for murder or manslaughter, so the best thing I could get him on was the Sanitary Code, because he had been selling unwholesome fish. He was punished with a \$50 fine. But when he told me that he was in this country illegally, I said to myself, "I'll send him back to Germany." So I telephoned the immigration authorities, and told them to send him back. I told them that it wasn't the \$50 that we were after, but we wanted to get rid of him. Well, they looked up the whole thing, and the report that came back to me was that although he said he was here illegally, they said that he was all right and that they could not deport him.

I tell you that it is a horrible situation. We have in New York 11,000 prisoners, and ten per cent of them are alien criminals, costing the taxpayers \$125 every year to support each one of them.

There has been a law on the statute books which says that persons committing a felony may be deported. I would like to have this organization go on record to ask your Congressmen and Senators whether this alien law is being enforced one hundred per cent after the prisoners leave the prisons. If I had my way, these people would stay in prison until the boat was ready to sail. It would not be, then, as it is frequently done that these people are put out on bail and then skip the bail.

What an economic saving it would be, and what a saving of sorrow to get rid of alien criminals!

Another way of getting rid of some of the crime is to carry out the system of probation. I am a firm believer in giving a boy or girl a chance on the first mistake. If you want to make a bad boy worse, send him to prison. There is no question about that. I was talking at the Academy of Medicine one night, and a presiding Supreme Court Judge, very flowery in his discourse, got up and said that when he sent a boy to prison, he sent him there out of a spirit of love, that he sent him there for treatment, not for punishment. Everybody applauded. My turn came, and I told the group how delighted I was to hear the learned Justice speak, and how nice it was to have him tell us that he sent boys away to Sing Sing out of love and for treatment. But if my memory serves me right, I have a boy working in the hospital at Sing Sing who is sixteen years and three months old, which is the minimum age for sentence, and he gave that boy a twenty-nine year sentence as a first offender. I can tell that Justice, and I could tell that group that no matter how bad the boy was, the probabilities are that living as he does now, with sixty per cent of the group having committed crime before, what he didn't know about crime before he entered, he knows today.

Every enlightened city and state is developing that probationary system. In Westchester, we have spent \$125,000 a year in the administration of our probationary system. In fact, it is done in Massachusetts. And what is the answer? I am told that hundreds of boys, with suspended sentences at Sing Sing, in fact ninety-two per cent of them, are making good on probation. What a salvaging! How much better it is than to send them to Sing Sing Prison, where they lose their citizenship, and where they are associating with men who have spent their lives in crime! How much better it is for the family!

Sometimes, people criticize Judges for placing people on probation, but everybody today in Westchester County knows that the Judge, before sentencing a boy or a man, has as good a detailed history of that person as it is possible to obtain, so that he is able to see the possibilities before he passes out the sentence or gives a suspended sentence. This is probably true in your State, too.

Another way, and the only way that seems to be any way of lessening crime—and we have got to talk of the future—is in the line of prevention. If the average age of the persons in prisons of the United States is twenty-three, that would mean that the boy who is thirteen years old today will be the criminal ten years hence. There is no question about that.

The only hope I see, so far as the present sit-

notion is concerned, is that there is little for those who have gone through the reformatory or the penitentiary, or the state prison from the standpoint of prevention. The only agencies that, to my mind, would be able to cope with the situation are the Boy Scouts and the Girl Scouts.

We have, in the United States 1,250,000 Boy Scouts and 317,000 Girl Scouts. And before I forget it, let me say a word about the Girl Scouts, because the women should be interested in this. During the last thirty years, we have been able to find that delinquency has increased to a greater percentage with the girl than with the boy.

But these boys and girls in the Scouts have an opportunity for self expression. They are taught to do a good turn every day which to my mind, is so important. They have an opportunity for outdoor life, for camp life, for nature and bird study, for study of the flowers and trees. They can get something out of it by getting together and, as I say, give expression to their leadership. I have never yet had a man in Sing Sing Prison who admitted to me he had ever been a Boy Scout. The Superintendent of the reformatory with which I am connected told me that he can recall, out of 30,000 boys but three he knew of definitely that had been Boy Scouts. The Judge of the Children's Court at St. Louis told me a few years ago after addressing a group interested in the Scout movement, that that year he had had seventeen hundred boys, from seven to seventeen years of age, with not a single Boy Scout in the group.

I had an interesting experience a few weeks ago. I came in my driveway one evening after doing an autopsy at Ossining. I carry an electric saw in my outfit, which is rather heavy. A little boy jumped over my wall, and he helped me out of my car with my things. So I pulled out a quarter, and I said, "Here's a quarter for you." He said "Oh, no, Doctor, that is one of my good turns." Then I asked him who he was, and found out that he was a twelve year old chap who lived in one of the poorer sections of Ossining, a little Italian boy. I said to him, "I wonder if your mother would allow you to come up and have supper with us to night at six o'clock?" I said six o'clock instead of seven so that it would be more nearly his time. Well, he said that he didn't know but that he would see if he could. He went home and took a bath and came back all shucked up. Well, I will tell you that I have spent a good many pleasant evenings, but I don't know of a more illuminating or a more interesting hour than I spent with that twelve year old boy whom I had never seen before. I learned that he was a Boy Scout and lived in the poorer section of the city, where the environment is none too good. To my mind, he is the hope of our civilization.

I became a Rotarian in 1921, because I happened to be out in Auburn one night, seated in the old Osborne Hotel there, and I heard a group of men singing and then I heard somebody get up and say that the club had a camp about six miles back of Auburn, where they were going to take a group of boys who normally wouldn't have a vacation. The thought came to me then that I had been living with the underworld for a long time and with boys and men whose environment had been none too good. When this meeting was over, I went into an adjoining room and joined up with the Rotarians. To me that was the secret of the criminal situation. I asked how Ossining could have a club because I told them that I wanted to associate myself with a group of men who would interest themselves in the boys, because the boys of today are the men of tomorrow. Within six months we had our own club and I am proud to say that in Westchester County, we group our funds together and take care of eight hundred boys, who, normally, wouldn't have an opportunity to develop their lives.

Speaking about the Boy and Girl Scout movement not only should we give of our funds, but we should become actively engaged ourselves, in trying to train these boys. I am pretty busy, and I know you are, too. But, there is nothing that I enjoy in the world more than I do to have a group of boys or girls in scouts. They are very enthusiastic. One time they told me that I could examine them in some subjects because they would get a merit badge if they passed.

I do not have a son but I have a daughter, who has just graduated in law. When she was in college, she used to come back every week for three hours to attend her Girl Scout troop.

I want to say to you that there is no agency that I can see which will be a greater force for lessening crime that is comparable with those institutions, the Boy Scouts and the Girl Scouts.

Lastly, because I must stop you and I can lessen crime if we pay more attention to our own children. We talk about the underprivileged boy and girl. As I travel around I often find that the underprivileged boy or girl is in our own household. I had a boy with me some few years ago, he was a college graduate, his father was and is today the Dean of one of the largest universities in the United States. He went overseas before the War and joined the Aviation Service in England and when he got into the War he transferred to our service. He met with an accident, sustained a fractured skull and was in the hospital for months in Paris. He came back and remained a couple of months here. In a college club in New York City, he carelessly forged a check and as a result of that forgery, he came to Sing Sing for three and one-half years. He had been there only

a few days when I took him into the hospital, as all the nursing is done by convicts. He had been there four days, when he said to me, "Doctor, this is a terrible place to be. I have been here four days, and I have had a lot of time to think. I have been thinking whether I would ever have been to State Prison if my mother had lived. My mother died when I was three months old and I was brought up by a governess. It never occurred to me that I loved my father as I pictured a boy should love a father, or that my father loved me as I pictured a father should love a boy. I don't want to blame father for my being here, but I have often thought that he was cold." So I wrote to the father and asked him to write to his son, because I believed he was worth salvaging. It was his first mistake. But his father wrote back in his letter to me, "He is dead to me." But I still wrote to the father, and I said, "Won't you come to Ossining and come to see me?" I am very careful in my correspondence in matters of this kind, I use my own personal letter head. I told him that he could come in and see me, and a little later on, somebody else would come in to see him. My idea was that if I could get him there, I could have the boy walk in. He wouldn't have to visit him in the other room, in the regular visiting room. But he still wrote to me, "I will never see him again in my life." Three years passed, and I realized that I had on my hands a college graduate, a brilliant boy who had the makings of a manly man. So I called him in to my office and I said to him, "Isn't there somebody on the outside who will interest himself in you?" He said, "Well, I don't know. I have an uncle, he hasn't written to me since I have been here, and I don't know his reaction. But I don't mind if you call him up." I went to my uptown office and called his uncle. I invited him down to my college club to have luncheon. I brought with me the letters I had received from his brother. We discussed matters pretty thoroughly. He said, "You know, my brother was always cold, he was always very firm. I remember when he was on the disciplinary committee at the University. If there was ever any misconduct and he made a ruling, he would never rescind his sentence." So I said to him, "Won't you come over and see the boy?" He said, "Yes, I will." So this good uncle came over every Saturday, and when that boy left Sing Sing, his uncle took him out to a western city. Eight years have passed, and today that same boy, whose father disowned him, is one of the most prominent and one of the most successful business men of that city.

You can imagine the pleasure that I have almost every year, when I go to the coast, I stop at that city so that I can shake the hand of a boy who made good, in spite of his father.

Here is another little incident which may interest you. I go to the Yale-West Point football game every year at New Haven. A year ago last fall, my wife and daughter were with me at the game. We sat there in the beautiful bowl with 80,000 people, more or less. Between the halves of twenty minutes, one of the fourth-class men, a boy who was going to graduate the next spring, came up the stairway, and immediately in front of us was the boy's mother, sister and father. He kissed his sister and his mother, and he turned to his father and extended his hand to his own father, and his own father never accepted it. Tears were in the eyes of the mother and sister. Tears were in all our eyes. Then, after but a few moments, the twenty-minute period was up, so the boy turned and kissed his mother and sister, and he said to his father, "Won't you forgive me?" His father never moved. I saw him go down and go to his group, and I said to my wife and daughter, "I wonder how many men I have known who have been in prison because of that type of relationship between a father and a son."

I would say to all men, "Don't think that all men who go to prison are roughnecks." You know, thirty-eight of them last year were college graduates, and one hundred and twenty-eight of them were high-school graduates, and a major portion of them had been through the grammar school. We have all types there.

So, let us have the confidence of our own children, and if we have that, there is very little danger of them becoming antisocial. I thank you.

DISCUSSION

PRESIDENT GAY: Thank you, Dr. Squire. Are there any questions, gentlemen?

DR. SQUIRE: I would like to add that there is often a lot of criticism over the management of prisons, and a lot of people oppose athletic contests in prisons. You will be interested in this, which is a true story.

We have a football team that plays outside teams on Sunday, and the fifty cents that people pay to see the game goes to buy uniforms and footballs, and in the summer, this money furnishes baseballs and bats and uniforms for the baseball leaders. I think it was last October that I was watching one of the games on a Sunday afternoon. We have the same people referee and umpire the games that umpire the West Point games the day before, in other words, if there is a game at West Point on Saturday, the umpire comes down and umpires the prison game on Sunday.

We had a team that came to us that played rough football, so much so that you could detect it during the play. The Sing Sing team, by the way, is called the "Black Sheep" team. One of the players on the Sing Sing team was thrown, and after being thrown, one of the outsiders walked on him. He was unconscious, but the opponent walked on him just the same. The referee, seeing it, put the fellow out of the game for playing rough. When the fellow

came to be inquired as to where the fellow was and he was told that he was put out of the game because the referee thought he intentionally stepped on him. He went to the referee and said "I don't like that. I don't think he meant it. He is a good player. He is the best player they have and I think he ought to be put back." He was the captain of the Sing Sing team. So they finally persuaded the referee to put the fellow back in the game. After the game and on the way out to the washhouse where they were going to take a bath and change clothes I walked down to this boy and I said "That was a wonderfully fine thing for you to do. You were walked on by somebody who threw you violently and still you had that sporting spirit that you wanted to play the good game and you went over to the referee and asked him to bring the fellow back into the game." He turned to me and he said, "Doctor, I have been playing football two years and I can't help but believe that had I had an opportunity to play football on the outside of prison I never would have been in prison. It has taught me the value of self-control."

To me that compensated any criticism that I have heard that maybe the fellows shouldn't play football inside the prison.

DR. OVERHOLSER. I am interested in Dr. Squire's reaction to the question as to how prevalent mental deficiency is among the inmates that he sees.

DR. SQUIRE. Well, of course in Sing Sing we do not receive for the most part, this type of person. We have an institution set aside for mental defectives. In other words the law is that if a judge has a person before him who is believed to be mentally defective generally he is not sent to the prison but he is sent to this institution. We have nine hundred at this institution. If one should come to Sing Sing prison the examining physicians usually transfer him for mental defectiveness.

That is taken care of very well in New York State. I do not know whether other states do this or not.

DR. OVERHOLSER. Massachusetts had the first law and New York had the first institution.

DR. SQUIRE. I will say this. I do think that no state has a better reputation for the management of penal institutions or advanced thought in penology than you have right here in your own state. I think that there is no question about that. It is so much better that we have adopted your Sanford Bates whom I know very well, and who is a progressive penologist.

DR. BARRETT. I am especially interested in the question of probation which evidently is becoming one of the outstanding means of taking care of the

early criminal and the fact that probation is available for first offenders has a tendency to lead to that first offense.

DR. SQUIRE. I don't feel so. I have never been in sympathy with the Baumes law in New York. We had a Senator from Newburgh who was appointed Chairman of the Committee on the recodifying of the criminal code as far as punishment was concerned. His idea was that we were having so much crime that more time should be given in prison. So he advanced sentences where they were five years he made it ten, etc. But instead of lessening crime, it increased it. It isn't the severity of the sentence that will curb crime. It is swift justice that will do it. If a fellow committed a crime and he knew that he would be punished for it, I believe that he would think a second time before doing it again. You and I know that if we were in prison a day we would be cured. It isn't the length of time. We would be more cured in a short time than we would be if we stayed there ten years.

But, we are too slow in justice. We don't apprehend ninety per cent of the crime in this country.

I had to laugh the other day. I was talking to the Chief of Police and he was telling what a wonderful thing it was to go about putting tags on parked cars for sixty minute parking. He had all the police forces doing it. I said to him "For goodness sake here is a list of murders in this town. Why don't you get the murderers?" I gave him a whole sheet full of them. I said to him "The taxpayers want these murderers solved. I have never heard of a parked car killing anybody in this County."

And we are paying dearly. Granted that the Judge may fine you a dollar for your parked car but that is of no moment when you consider a whole list of unsolved murders.

Where we are slow is in our crime detection. We are way behind the European countries. I was privileged to spend a couple of weeks in London, Vienna, and Paris in their crime detection laboratories. And when they tell you that they apprehend eighty per cent of their criminals and when you know that we apprehend only ten per cent it is mighty serious.

There are no politics over there. It wouldn't make any difference if you were the king. If you committed an offense you would be punished. They respect police officers over there and they respect the law. They don't publicize crime. I was in London one time while a murder case was being tried. I had never been to a murder trial over there so I attended part of the trial. I got on the ship at Southampton to come back to the States and seven weeks later I saw where the fellow was hanging. Believe me, over here he wouldn't have been caught yet.

EXCERPTS FROM THE BULLETIN OF THE MEDICAL SOCIETY OF THE STATE OF NEW YORK

Last year the common cold cost more than \$5,000,000 in loss of wages. More absences from work are due to it than to any other illness. When you have a cold stay home, and if it is severe remember pneumonia as a possible danger.

Rudolph Virchow who gave to biology the impetus which formed the foundation for the study of heredity was interested enough in politics to be a member of the German Reichstag many years of his life.

The increasing number of cases of trench mouth is attributed by Dr. Don C. Lyons, of Jackson Mich., to uncleanness in glasses used in taverns and eating establishments serving alcoholic beverages.

Doctors think of what they call the "clinical picture" in studying their cases. "What is spoken of as a clinical picture," said Dr. Francis W. Peabody, former Professor of Medicine at Harvard Medical School "is not just a photograph of a man sick in bed. It is an impressionistic painting of the patient surrounded by his home, his work, his relations, his joys, sorrows, hopes and fears."

CASE 22061

PRESENTATION OF CASE

A thirty-one year old Italian toolmaker was admitted complaining of a persistent cold

About one month before entry the patient developed a slight cough productive of a small amount of yellowish sputum. This began to subside a week later, at which time he attended a carnival. On the following day he had "chills" and three days later developed fever and malaise. Thereafter he was confined to bed. For a few days following this exacerbation his cough was productive of brownish sputum but since had continued to be yellowish in color with an occasional foul odor. There were infrequent night sweats, considerable anorexia, and some insomnia. The slightest exertion caused shortness of breath.

Physical examination showed a well-developed and nourished young man who looked moderately ill. The skin was moist and warm. Chest expansion was limited on the right side. Distant bronchial breathing was heard in the right infraclavicular region. There was lessened tactile fremitus, dullness, distant bronchial breathing, and high pitched exaggerated vocal resonance over the right lower chest posteriorly. An inspiratory friction rub was audible in this region and a pleuropericardial rub was said to have been heard over the precordium. Examination of the heart was otherwise normal. The blood pressure was 110/70. There was questionable clubbing of the fingers.

The temperature was 99°, the pulse 110. The respirations were 30.

Examination of the blood showed a red cell count of 4,900,000, with a hemoglobin of 85 per cent. The white cell count was 9,800, 81 per cent polymorphonuclears. A single sputum specimen was mucoid in appearance with scattered blood flecks. A single acid-fast bacillus was found.

X-ray examination of the chest showed dullness in the lower half of the right lung field. In the upper portion of the chest dullness was more marked in the hilar region.

On the afternoon of his second hospital day

the patient suddenly became markedly dyspneic, cyanotic, and apprehensive. The respirations increased to 50 and the pulse became weak with a rate of 170. The chest signs were unchanged. The patient expectorated a small amount of strongly tenacious sputum but his condition remained unchanged. A white blood cell count was 27,000. An x-ray showed, in addition to the previous findings, dullness involving the right apex and infraclavicular regions and marked displacement of the trachea to the right. Despite the administration of small doses of morphin and the use of an oxygen tent the patient's condition remained unchanged. The temperature rose to 103°, and he died about twelve hours after the onset of the acute episode, at the beginning of his third hospital day.

DIFFERENTIAL DIAGNOSIS

DR EARLE M CHAPMAN Will you please demonstrate the x-rays, Dr Holmes.

DR GEORGE W HOLMES I do not understand the x-ray note. It is a bit ambiguous. The difference was twenty-four hours. This film was taken from the front of the chest apparently in the upright position. This one was taken with the patient lying on the back, a portable film. The difference in appearance may be due to difference in position of films or it may be due to shift of fluid in the pleural space. I rather think it is the former and not an actual change in the lung condition in this interval. There is a considerable area of dullness here and yet the heart is not displaced away from it. In fact, if anything the heart is toward the lesion. I am not able to make out the position of the diaphragm on either side. Usually when there is no fluid present you can see the diaphragm even though the lung is collapsed. This failure to see the diaphragm may be due partly to the quality of the film—both films are poor. I think we can say that the left lung is normal and that the heart is not enlarged. It is displaced somewhat toward the lesion. The lesion in the lower part of the chest must be due in part to collapse of the lung. Air is not getting into the lower half of the chest in the normal way. I do not think that would explain the whole picture however. There is either some fluid in the pleural space or consolidation in the lung, as well as partial collapse.

DR CHAPMAN I must say that this final report is much different from that appearing in the abstract. You did not comment on the trachea, Dr Holmes.

DR HOLMES I would not be at all concerned about the displacement of the trachea. It may be due to rotation, although it does look as though it were displaced.

DR CHAPMAN We can say it did not push it away but seemed to contract the mediastinum toward the side of the lesion.

To go back over the history, there are two or

three points that are of interest to lead to the summary of the situation. The first thing is he is thirty-one years old and an Italian tool maker. Offhand I do not think of any industrial bazaar in toolmaking except in the granite industry where men are exposed to large amounts of silica dust. We do not know where he was a toolmaker.

A month before entry he complained of the onset of cough and chills appeared a week later. He was ill first and then went to a carnival came back, and the following day took to his bed. He was in bed three weeks before he came to the hospital. The next point is that he had occasional foul sputum. I suppose we might assume that he had intermittent bronchial obstruction. Severe shortness of breath was an outstanding complaint. Upon physical examination we found he had distant bronchial breathing in the right infraclavicular region and over the right lower lobe there was dullness diminished tactile fremitus and distant bronchial breathing. These are the signs of partial obstruction to the bronchus, with partial collapse. However the physical finding of increased vocal resonance is rather confusing and I do not see how it fits unless there is a cavity. In other words, it may be amphoric breathing but it is hard to tell. However, the signs are consistent with partial obstruction to a bronchus with some consolidation or collapse of the lobe.

There was questionable clubbing of the fingers. We must remember he had been ill four weeks and this may be true clubbing beginning after four weeks' illness.

There is no mention of examination of the abdomen or glands. We do not know whether the spleen was palpable or not.

When we come to the laboratory examination I would like to know whether the Hinton test was done. It is hard to attach much significance to the finding of a single acid fast bacillus because objects resembling acid fast bacilli can easily be seen on a scratched piece of glassware so it is important to have clean glassware with no scratches.

As to the x-rays, what happened, following this terminal episode, is that there was a spread of dullness over the upper lung field and the mediastinum contracted toward the side of the lesion rather than away from it.

I believe that this man had signs of partial obstruction to his bronchus with probable collapse or consolidation behind it and in this area later a lung abscess formed. The rapidity of the process and the progression of the symptoms as contrasted with the first case are in favor of lung abscess. In favor of this is the occasional foul sputum and the changes in physical signs. The x-ray is consistent with it and Dr. Holmes hears it out in saying that it is also consistent with collapse or partial collapse of the right lower lobe.

There is no history of aspiration of a foreign body unless we assume that an Italian at a carnival may have inspired a foreign body. I do not know. As Dr. Lord has pointed out in a review of a series of cases in about fifty per cent of the patients lung abscess is attributable to aspiration but in thirty-three per cent of them the onset is insidious and no cause can be found.

The next step is to look for the cause of the obstruction of the bronchus to the lower lobe.

"In the upper portion of the chest dullness was more marked in the hilar region." That is very suggestive the way it is reported here but Dr. Holmes did not stress it as in the report. What do you think there is in that area, Dr. Holmes?

DR. HOLMES: I think that that statement means nothing. If you read the one in the report the dullness was more marked in the hilar region and has nothing to do with dullness in the upper part of the chest.

DR. CHAPMAN: Then, as a cause of obstruction we must think of foreign body, possibly aspirated at the time of the carnival and an unresolved pneumonia, the process going on while the man kept on his feet and finally leading to a lung abscess.

Another possible cause is neoplasm. He is rather young, thirty-one, for carcinoma, but it is possible that a lymphoblastoma in the region of the right bronchus could cause pressure and partial collapse and lead to pneumonia. The physical examination, however, does not support this. There is no report of glandular enlargement, no evidence of disease of the lymphatic system.

Syphilis we must think of, and there again there is no Hinton report. I think we must exclude it assuming it is negative.

Tuberculosis is a disturbing point. The finding of a single acid fast organism I am inclined to discount. The first picture does not show anything to indicate tuberculosis above the fourth rib, does it, Dr. Holmes?

DR. HOLMES: No.

DR. CHAPMAN: I think tuberculosis is quite unlikely. Recently Dr. Hawkes, a former house officer here, reported an epidemic of trichinosis in Italian people and his first case pursued a course not unlike this and died of unresolved pneumonia of the right lower lobe. It was not until after the second week of the disease that eosinophilia appeared. In his case the eosinophilia was the best lead but in our case no report is made of the differential count. It simply says that there were 81 per cent polymorphonuclears. No differential count was done on the count of 27,000. Although trichinosis should be considered, it is quite unlikely.

Lesions in the esophagus such as traction diverticulum would lead to erosion through the

bronchus with this picture. No history of difficulty in swallowing was indicated.

Apparently the pericardium is involved, at least the parietal surface, as he had a pleuro-pericardial rub.

The final episode may give a clue to the whole thing. It is a mysterious one. The physical signs suggest massive collapse and the mediastinum shifted over to the side of the lesion but there is no x-ray evidence of further collapse there. He may have had a sudden extension resulting from rupture of encysted fluid, probably purulent, into the lung tissue and perhaps into the pleural cavity. The x-ray was taken lying down and such an episode would account for the diffuse dullness over the upper lobe. Consistent with this is the rise in white count, the marked shortness of breath and the rapid exitus.

In conclusion, my diagnosis is lung abscess with some process partially obstructing the bronchus to the right lower lobe. Originally because of the report on the paper I thought it was neoplasm and possibly, because of the report of density of the hilus, lymphoblastoma or sarcoma, but the x-ray does not bear that out, nor do the remaining physical findings, so that I am left with just that diagnosis alone.

DR DONALD S KING: I saw this patient the day he was admitted. In addition to the physical signs as given in the record I found a definite unilateral wheeze. As Dr Chapman has told you the recorded physical signs were those of partial bronchial obstruction, and the musical râles limited to one side seemed to me further evidence of such a condition. When I examined the patient there was also a change in the breath sounds, and instead of much diminished breathing there was bronchial breathing at the right base so that I felt justified in making a diagnosis of collapse with an open bronchus. We were then faced with the question of what was causing this obstruction. The first thought naturally was intrabronchial tumor, and I think we did mention tuberculosis as a possibility because we have recently been impressed by the frequency of a tuberculous process within the trachea and bronchi. We have had two cases this fall with collapse of the upper lobe who were bronchoscoped with the expectation that a tumor would be shown. Neither case showed outcropping but the mucous membrane was abnormal in both cases and a biopsy specimen was diagnosed as tuberculosis. A third case showed only slight changes in the parenchyma of one lung. The other lung appeared normal. Because of a persistent positive sputum artificial pneumothorax was instituted on the affected side, but in spite of eight months of such treatment with a complete collapse, the patient continued to raise a large amount of sputum containing many tubercle bacilli. Bronchoscopy was finally performed and showed

the left main bronchus almost filled by tuberculous granulation tissue.

The day after this first examination I received a telephone call in which the sudden change in the clinical picture was described. Because of what we had found on the previous examination I thought that there had probably been a sudden complete occlusion of the bronchus and that we were dealing with a massive collapse. The patient was then examined to see if we could find evidence of complete bronchial obstruction sufficient to warrant an emergency bronchoscopy. We also had in mind a possible emergency artificial pneumothorax in order to relieve the symptoms which are sometimes caused by an acute massive collapse. Physical examination and x-ray, however, did not give us evidence of such an obstruction so that the advice was for morphia and oxygen. Although the patient was relieved by these measures he died a few hours later. We were not prepared for the autopsy findings.

CLINICAL DIAGNOSES

Lobar pneumonia
Neoplasm?
Tuberculosis of the lung?

DR EARLE M CHAPMAN'S DIAGNOSIS

Abscess of the lung

ANATOMIC DIAGNOSES

Tuberculosis, chronic, right upper lobe
Acute tuberculous pneumonia, right lower lobe
Pulmonary embolus
Pulmonary infarction, early, left lower
Pulmonary atelectasis, right upper

PATHOLOGIC DISCUSSION

DR TRACY B MALLORY: This man had his sudden terminal episode two or three days too early for the convenience of the hospital. I think if they had had more time to investigate they would have come closer to the diagnosis. He came to us with a number of questioned diagnoses on the death report varying from lobar pneumonia, through abscess, cancer of the lung, to tuberculosis. What we found was a very extensive severe tuberculosis, nothing else. He had an old fibrous lesion at the apex, evidently the source of the infection, and then an acute tuberculous pneumonia which involved primarily his lower lobe on the same side, approximately three-fourths of that lobe was solid with tuberculous pneumonia, almost lobar distribution. There were scattered spots through his various other lobes with occasional lobules of tuberculosis, evidently a pneumonia spread by the air passages rather than through the blood stream. We found nothing to explain the bronchial plugging except the pres-

ence of a large amount of thin mucoid exudate which could easily come and go and produce a varying picture. The right upper lobe showed extensive atelectasis.

The terminal episode was still more of a complete surprise. That consisted of a large pulmonary embolus which lodged in the artery to the left lower lobe.

A PHYSICIAN Any evidence of tuberculosis in the left lung?

DR. MALLORY There was one spot way down at the left base where a group of several lobules showed pneumonic exudate, with scattered individual lobules elsewhere, but no very large amount.

A PHYSICIAN Was there any pleural effusion?

DR. MALLORY About 100 cubic centimeters.

A PHYSICIAN Where did the embolus come from?

DR. MALLORY We do not know. We were restricted to the chest. Such cases usually in my experience show thrombosis of the deep veins of the leg, however.

CASE 22062

PRESENTATION OF CASE

A fifty-seven year old unemployed Syrian entered complaining of hematuria.

Twelve years before admission following right lumbar pain a stone was removed from his right kidney. He remained well until seven years before admission when another stone was removed from the same kidney. There were no symptoms following the second operation until three months before admission when he developed burning pain upon micturition, and cloudy urine. At about the same time he began to have frequency six to eight times and nocturia one to four times. Two months before admission he began passing small clots of blood which continued until his urine became pink and more recently deep red. On several occasions during the week before entry he had been unable to urinate until a clot was passed. During this two month period he had pain in both kidney regions. On the morning of admission he entered the Out-Patient Department with acute urinary retention. Eighteen ounces of red urine was obtained and an attempt at cystoscopy in the Out Patient Department was fruitless because of the large amount of blood in the bladder. During the past three months his appetite had been poor and he had lost about 30 pounds in weight.

His marital and family histories are non-contributory. He had had an attack of gonorrhea thirty years before entry.

Physical examination showed a fairly well developed and undernourished, pale, dehydrated

man with a slight trace of acetone on his breath. The skin and mucous membranes were pale. Many of his teeth were missing. The heart and lungs were negative. There was a hard questionable rough mass about 8 centimeters in diameter situated just above the umbilicus which was taken to be the bladder. There was a scar in the right flank. The blood pressure was 130/70.

The temperature was 100.1°, the pulse 112. The respirations were 30.

The urine was red and showed a brown tint for sugar. The sediment was loaded with red blood cells and also contained a few white blood cells. Examination of the blood showed a white cell count of 10,900. The nonprotein nitrogen of the blood was 51 milligrams. The blood sugar was 456 milligrams.

A plain abdominal film showed a slightly enlarged right kidney outline. The left kidney was very large and elongated and overlying its lower pole were three shadows having the appearance of stones. There was also a shadow two centimeters in diameter overlying the lower right sacrum apparently in the course of the right ureter. There were also two small faint shadows in the region of the gallbladder. Intravenous dye appeared on the left in good concentration. On the right there was very little evidence of secretion. The upper urinary tract on this side appeared considerably dilated. On the left there was gross dilatation of the kidney pelvis and major calices with clubbing of the minor calices. The bladder was not visualized. The lung fields were clear.

On the second day bilateral nephrostomies were performed. A cystoscopy was not very satisfactory but there seemed to be marked edema and a large amount of blood clot clinging to the bladder wall. There were some areas that suggested neoplasm. Five days later a suprapubic cystotomy and fulguration of the bladder tumor were performed. Following operation there was a sharp rise in temperature. In spite of insulin treatment, 10 to 30 units a day, his blood sugar remained fairly elevated. His nonprotein nitrogen rose to 81. The CO₂ combining power was 36.4 per cent. He rapidly failed and died twelve days after admission.

DIFFERENTIAL DIAGNOSIS

DR. E. ROSS MINTZ There are a number of diagnoses given to us in this history practically ready made. Among them are recurrent nephrolithiasis, diabetes mellitus, and a vesical neoplasm. It is not unusual for patients with one kidney stone to form others. It is not common, however, for renal stones to produce gross hematuria, although they may very well do so yet it is not the rule. The character of hematuria that one sees in calculus disease of the kidney is usually a pinkish urine or microscopic hematuria, and not hematuria with

clots, clots so large as to produce obstruction to urination, and fill the bladder so completely with blood. If the hematuria is renal in origin one must consider the question of renal neoplasm associated with stones. This is fairly common in the papillary and epidermoid carcinoma of the pelvis of the kidney and would fit in with a question of a tumor in the bladder, yet the probability is that there is no renal tumor.

I notice there has been no mention of what the serum calcium and phosphorus showed in this particular case, although it probably would not have any relation to the present condition, yet it would be interesting to know if the patient had evidence of hyperparathyroidism.

A flat plate of the abdomen showed a number of shadows in the left renal pelvis which had the appearance of stones, and there was also a shadow in the right lower quadrant in the course of the right ureter. Intravenous neopax was not excreted by the right kidney, but was by the left. In all probability the patient had a small stone in the lower end of the right ureter which probably completely obstructed it. This would fit in with the finding of a large kidney on the right side. It is interesting to note that at no time were there any symptoms of left renal colic. On cystoscopy a bladder tumor was found. It would be important to know just what type of tumor was found and the size and location of the tumor. It may well be that a vesical neoplasm could obstruct the right orifice accounting for the nonfunctioning kidney on that side.

The high nonprotein nitrogen could be explained in various ways. The patient was evidently acidotic, for the carbon dioxide combining power was 36.4 per cent. The elevated nonprotein nitrogen might have been due to marked renal damage caused by blockage in the right ureter and stones in the left, which may or may not have completely blocked the ureteral pelvic junction, or may have been due to an overdistended bladder with back pressure. It is, however, unusual with that amount of nitrogenous retention and kidney damage and also considering the patient's age, fifty-seven, to have the blood pressure only 130/70, taking into consideration that on physical examination no cardiac lesion was found. I am also surprised to see that the temperature is no higher, and also that there are no more than a few white cells in the urine, for it is known that diabetics are very prone to infection. It makes one wonder if the patient has a completely blocked-off kidney on the right with a pyonephrosis behind it.

It would be interesting to know just what was obtained and what was found when the bilateral nephrostomies were done. It would seem that if the hematuria were coming from the kidneys the nephrostomy tubes should have

been able to take care of it without having the bladder fill with blood clots five days after the operation. It would make one feel that without question the hematuria was vesical in origin and probably the tumor in the bladder was more extensive than the record of the operative findings indicates.

Nephrostomies are not without dangers. I have seen excessive bleeding, sepsis in the kidney, and in one particular case a renal infarct following this operation.

One begins to wonder whether the patient's temperature of 100.2°, the white count of 10,900, and the blood pressure of 130/70 indicate the real pathology present. It sounds to me as though the patient were in extremis, and confirmatory evidence for this can be deduced from these three findings. Sepsis is unquestionably present and probably will be found in the right kidney either in the form of a pyonephrosis or in the form of smalliliary abscesses. Of course, there will be sepsis in the left kidney.

I believe the lesion in the bladder is an epidermoid carcinoma. As no calcium and phosphorus blood studies were done, one cannot say whether the patient has a parathyroid tumor. A history of recurrent bilateral stones is highly suggestive of it, although a fair percentage of cases with bilateral stones have been proved to have no pathology in the parathyroid gland.

CLINICAL DIAGNOSES

Bilateral renal calculi
Carcinoma of the bladder
Diabetes mellitus

DR E. ROSS MINTZ'S DIAGNOSES

Epidermoid carcinoma of the bladder
Bilateral nephrolithiasis
Diabetes mellitus
Pyelonephritis

ANATOMIC DIAGNOSES

Epidermoid carcinoma of the bladder, bilateral
Hydronephrosis
Pyelonephritis
Nephrolithiasis
Operative wounds. Cystotomy and bilateral nephrostomy
Septic spleen
Arteriosclerosis
Parathyroid cyst

PATHOLOGIC DISCUSSION

DR TRACY B. MALLORY. The autopsy findings confirm the double diagnosis of nephrolithiasis and carcinoma of the bladder. The cavity of the bladder was almost completely filled

with a large, partly necrotic cauliflower mass, which was attached to the posterior wall. It did not involve the mouth of either ureter. On microscopic examination it proved extremely undifferentiated, but a suggestion of cornification here and there made us feel that it should be classified as an epidermoid. The right kidney pelvis was greatly dilated and the nephrostomy wound opened into it. Practically no recognizable renal parenchyma could be identified. The left kidney was extremely large, weighing 650 grams. This was due probably in part to compensatory hypertrophy, and certainly in part to an extensive infectious process since on section innumerable small abscesses were evident. The pelvis contained five stones, varying in size

from three centimeters to four millimeters in maximal diameter. The renal vein was partially occluded by a fresh thrombus. The patient showed a typical septic spleen which weighed slightly over 700 grams, was very soft and flabby with invisible markings. The heart was essentially negative except for numerous sclerotic patches in the coronary arteries and a moderate degree of calcification at the bases of the aortic cusps. It was not felt however that these findings would have produced any symptoms. The parathyroids were examined with care but proved negative except for the presence of a small cyst in one gland. Cysts of this type are fairly common incidental autopsy findings and have no functional significance.

PROTAMINE INSULIN

ANY advancement in the treatment of diabetes is "news." No better proof of this is required of the vast multitude of diabetics in the country and of their relatives and friends than the prominence given in the press recently to the Hagedorn protamine insulin. Unlike many announcements of new remedies, this would appear to err on the side of conservatism, because the implications which must follow a control of the blood sugar of diabetics for twenty-four hours are so far-reaching. If the blood sugar is normal, the blood fat, the reaction of the blood, the glycogen storage in the tissues presumably will become normal too, and in fact, the diabetic will approach still more closely the normal state. As a result, complications should decrease and the premature arteriosclerosis of the diabetic, which insulin had deferred to a considerable extent, should begin to be a thing of the past.

It is true that the present preparation of protamine insulin will not act quickly enough in coma and will not enable the patient to eat

carelessly. However in combination with regular insulin it will allow adequate diets, and by controlling the disease not only prevent the onset of hyperglycemia with the danger of coma, but hypoglycemia with the danger of reactions. Results to date of studies now in progress suggest that there will result a preparation of protamine insulin which can be used exclusively—without the aid of regular insulin.

Protamine insulin promises to work almost a revolution in the treatment of diabetes. To the Naunyn, Allen, and Banting Eras, our friends at the George F. Baker Clinic tell us that we now must add a fourth, the Hagedorn Era.

It is no secret that the new protamine insulin came to Boston first for trial, because of a hint from a Boston medical Nobel Prize winner. A year ago in Copenhagen he met another Nobel medalist, Professor Kiøgh, who is one of the Trustees of the Steno Memorial Hospital, and there was introduced to Dr. Hagedorn.

Hagedorn is a familiar name to doctors. The present Hagedorn is known the world over because of the Hagedorn-Jensen technique for estimation of the blood sugar. His originality and versatility are well-known. For some years he has been in charge of the laboratory in Copenhagen in which insulin is manufactured for the Scandinavian countries, Finland, Norway, Sweden, and Denmark, under the supervision of the Danish king. The profits from the sale of insulin have been set aside for research, both in an adjoining laboratory and in a hospital of twenty-two beds, chiefly for diabetics, just across the street. Dr. Hagedorn presides over all three institutions, and in each his inventive genius is apparent.

Commercial insulin is an acid—insulin hydrochloride—with a pH of 2.4. It thus radically differs from the reaction of the blood which is alkaline and has a pH of 7.4. Hagedorn conceived the idea of combining insulin with a base, and for this purpose resorted some years ago to trials with the various protamines, produced first by Miescher in 1868 and first used as protein precipitants by Kossel in 1890. A product near the pH of body fluids naturally would diffuse more slowly than one whose reaction was acid. We understand Hagedorn went through a laborious process in his search for the protamine he wanted, and suspect it required all the patience of an Ehrlich in his discovery of 606. Oddly enough, the protamine in the sperm of fish, and particularly in that of *salmo iridus*, rainbow trout, an American fish, proved the best to use. At present regular insulin and the protamine are dispensed in separate bottles and must be mixed before injection. A precipitate forms, but this is of so fine a character that it readily passes through a hypodermic needle.

and indeed causes no more local reaction than ordinary insulin

This new discovery in the treatment of diabetes wakes us all up. It makes us realize how rapid progress in medicine has grown to be. Galen described his two cases of diabetes in the second century, but it was not until the sixteenth century that Paracelsus evaporated the urine of a diabetic and observed that it left a large residue of "salt." Rollo instituted the dietetic treatment of diabetes only 140 years ago. When Toronto gave us insulin, we became altogether too smug in our satisfaction that diabetes were living twice as long as half a generation ago and not dying, on the average until they reached sixty three years. We were hardly prepared for a new therapeutic diabetic milestone so soon and it is for this reason that Hagedorn's protamine insulin upsets all our calculations.

Best of all, this new discovery of Hagedorn emphasizes anew that it is brains not bricks and mortar, which bring progress in medicine. We do not need more beds in our hospitals anywhere nearly so much as we need more brains. Think of what already has been wrought through this new method of treatment. It has given hope literally to millions of diabetes throughout the world and they are stimulated to keep alive a few months longer to reap its benefits. No extra hospital beds will be required!

In "Man the Unknown" Carrel refers to diabetes, and his remarks are most pertinent to the present occasion. "For instance insulin brings about the disappearance of the symptoms of diabetes. But it does not cure the disease. Diabetes can be mastered only by the discovery of its causes and of the means of bringing about the repair or the replacement of the degenerated pancreatic cells. It is obvious that the mere administration to the sick of the chemicals which they need is not sufficient. The organs must be rendered capable of normally manufacturing these chemicals within the body. But the knowledge of the mechanisms responsible for the soundness of glands is far more profound than that of the products of these glands. We have so far followed the easiest road. We now have to switch to rough ground and enter uncharted countries. The hope of humanity lies in the prevention of degenerative and mental diseases, not in the mere care of their symptoms. The progress of medicine will not come from the construction of larger and better hospitals, or larger and better factories for pharmaceutical products. It depends entirely on imagination on observation of the sick, on meditation and experimentation in the silence of the laboratory."

If Carrel is correct and brains are important in the field of medicine, how long will it take

for us plain people, following the lead of Presidents Lowell and Conant, to demand that brains shall be recognized in every field of human endeavor?

HOUSE BILL NO 34

THE hearing on this bill was conducted on January 23, and was sponsored by Dr Stephen Rushmore, Dr Charles E Mongan, Dr Frank H Lahey, Dr Francis R Mahony and Dr Walter P Bowers

The opposition was conducted by representatives of the College of Physicians and Surgeons and the Massachusetts Osteopathic Association.

There is an opportunity for all physicians interested in this matter to use influence with members of the Legislature before the report is considered by the General Court.

Persons interested in having House Bill 34 become a law may well ask questions as to how their hopes may be realized. It is to the interest of nearly every person in the state to have the bill passed, but on the other hand few persons are interested in doing anything about it. It is a problem of practical politics.

The first consideration concerns the importance of the issue. Does it really make any difference what kind of doctors are permitted to practice in Massachusetts? Is disease after all something which can be controlled by intelligent actions? Can one, by taking thought, add years to the span of his life? Yes, is the emphatic answer to each of these questions, and yet one finds many persons whose activities suggest that their answer would be No.

There is no doubt that better health is possible, that better protection against disease is practicable, that better protection against incompetent and unscrupulous physicians can be obtained if the citizens are willing to provide the means. It is not a question of increased expenditure of money. It is merely by exercise of duly constituted authority to secure protection, legal enactment to increase the scope of the work of machinery already created and functioning.

In order to secure this legal enactment it must be made clear to the legislators that what far sighted statesmen sought years ago has become a popular demand. It must be made clear to the citizens just what is at stake. They must understand that it is their health which is involved, their protection which is sought, and they must be persuaded that a real danger exists.

There is little need of new facts hitherto unknown. New facts would merely support what is known. It is rather a problem of bringing to the attention of voters throughout the state facts which have been well known to a small

group for years. As the knowledge is spread there will be attempted rebuttal by misrepresentation of fact and motive and recriminations will be rife.

The persons best qualified to take the leading part in spreading knowledge of the facts are the physicians. To them, in spite of much misrepresentation and abuse for the doctor, the sick instinctively turn for knowledge about disease and its relief. They, better than any other group, can lead the way. Yet comparatively few physicians are keenly aware of the facts in the present intolerable situation. Massachusetts has the lowest statutory standards of practice in the United States, and there are admitted to practice in Massachusetts each year a considerable number of physicians whom no other state in the Union would regard as qualified even to be admitted to the examination for licensure.

There is presented then to the medical profession a duty and an opportunity to enlighten the public, so that public opinion will demand that Massachusetts should give to its citizens at least as much statutory protection as the other states give to their citizens.

'Terias irradiant! Let them enlighten the earth! Let the medical profession do its part in enlightening the voters of Massachusetts.'

The Massachusetts Medical Society

THE SURGICAL SECTION

THE Surgical Section of the Massachusetts Medical Society will hold its annual session in Springfield at 9:30 on the morning of June ninth. Dr. Mont R. Reid, Professor of Surgery at the University of Cincinnati, has accepted an invitation to address the Section, and has chosen to speak on the subject of "Wound Healing." Dr. Reid and his colleagues have been conducting some researches on this very fundamental problem, a problem of interest not only to surgeons but to all practitioners of medicine, every one of whom is concerned with the practical side of this subject in greater or lesser degree. Dr. Reid, noted for his painstaking work and for his surgical finesse, will present a paper which everyone should hear.

The balance of the program of the Section will be varied to appeal to the interest of different groups of surgeons, rather than limited to a symposium on one subject. The officers of the Section will be glad to receive, from members of the Society anywhere in the state, abstracts of papers which they deem worthy of inclusion in the program, and desire to present. Such requests should be submitted before March first, and will be carefully considered before the final program is selected.

With the increased tendency in recent years

toward limitation and concentration of interest and fields of activity among doctors, it should be emphasized that, just as surgeons would be better surgeons if they attended more scientific meetings on purely medical subjects, so also will those doing medical work profit by attendance at surgical meetings.

DIABETES IN PREGNANCY

Until the discovery of insulin diabetes in pregnancy was a very serious complication. Fortunately diabetes was a definite cause of sterility, few diabetics becoming pregnant. Fortunately again diabetes was a cause of miscarriage, so that actually very few diabetics who became pregnant ever succeeded in reaching term, and among those who did reach term most of the babies were born dead. Because of the small chance of a diabetic having a living child and because of the extreme danger to the mother from coma and diabetic death, most diabetics were advised against becoming pregnant and those who did become pregnant were very often aborted.

Now, insulin has very largely changed this picture. Insulin is doing for the diabetic pregnant patient what insulin has done for the ordinary medical diabetic. It has increased fertility. It has saved the lives of children developing diabetes in their teens who, before the discovery of insulin, would never have lived to maturity, so that some of these diabetics have actually been delivered of living children. In consequence, insulin has materially increased the number of diabetic patients who may become pregnant. Under intelligent care, it has made pregnancy safe for these diabetic mothers, but not yet does it guarantee living children to every diabetic.

The problem of diabetes in pregnancy is primarily a medical problem. No one should think of caring for a sick diabetic, who is pregnant, who is not a trained specialist in diabetes. The obstetrician's rôle in this complication is not

important until delivery. The method of delivering these diabetics must be entirely individualized. One cannot intelligently say that all diabetics should be handled in one manner. If one believes that all diabetics should be delivered normally at term, certain diabetic babies are going to be lost. If one says that all diabetics should be delivered by Caesarean section, certain cases will be sectioned that do not need it. The mild diabetic requires very little care beyond that given a normal case, but the severe diabetic—the child who developed diabetes in the teens, who is alive today because of insulin, and who we feel should have only one or two pregnancies—does require very different treatment. Upon this latter type of case Caesarean section offers the best chance for the baby.

We know definitely that some babies die in utero after viability that might well be saved if delivered before intranatal death. Each case must be decided on its individual merits.

It is not nearly enough to call a case successfully treated when a living baby is delivered. Experience has taught that babies of these diabetic mothers are most unstable. After birth they have very strange metabolic reactions—some of them have demonstrated a remarkable condition of hypoglycemia. These babies must be nursed and cared for by one trained in diabetes as carefully as the mothers have been cared for during the pregnancy. Consequently one sees that the problem of diabetes in pregnancy is threefold.

1 A medical problem. The internist specializing in diabetes must have intimate control of the patient all during the pregnancy and labor, special attention being given those mothers who would not be living today were it not for insulin.

2 An obstetrical problem. The method of delivering these cases requires expert judgment, each case to be individualized.

3 A pediatric problem. Because of the severe metabolic disturbances that these newborn infants show, they must be under expert diabetic, pediatric care after birth.

If the diabetic who becomes pregnant is followed in this threefold manner, no mothers should be lost because of diabetes and the fetal mortality should become lower.

MISCELLANY

A RECEPTION TO DR. WILLIAM B. KEELER

In response to invitations extended by Dr. Charles F. Winsky public health officials, physicians, representatives of voluntary health organizations and associates of these groups met at the Myles Standish Hotel on the evening of January 29, 1936 to do honor to Dr. William B. Keeler, the newly appointed Health Commissioner of Boston.

A series of short selected articles by members of the Section is being published weekly. Comments and questions by subscribers are solicited and will be discussed by members of the Section.

Dr Wilinsky as host and toastmaster gracefully introduced the after dinner speakers and incidentally reviewed the history of the public health activities of Massachusetts and Boston, and as each speaker was presented, explained his relation to the accomplishments of the various health agencies of the state and city

Dr Keeler, at the close of the program, expressed his appreciation of the high honor conferred on him by his Honor Mayor Mansfield, and spoke with evident emotion of his regard and affection for Dr Mahoney, his predecessor, and for Dr Wilinsky, under both of whom he had served for fourteen years in the Boston Department of Public Health. He cordially invited the cooperation of organizations and individuals interested in the city's health problems and gave assurance that the doors of his Department will always be open for conferences and suggestions

The spirit of the occasion gives assurance that the capital city of Massachusetts will have an administration of its health problems in full accord with its traditions

AN HONOR TO DR HENRY POLLOCK

A testimonial dinner was given to Dr Henry Pollock at the Parker House, January 30, 1936, by about three hundred associates and friends of the Massachusetts Memorial Hospitals

In addition to his position as Superintendent of the Hospitals, Dr Pollock is an Associate Commissioner of the Department of Mental Diseases under Dr Overholser

RÉSUMÉ OF COMMUNICABLE DISEASES IN MASSACHUSETTS FOR DECEMBER, 1935

Disease	Dec, 1935	Dec, 1934	5 Yr Average*
Anterior Poliomyelitis.....	21	1	12
Chickenpox	1537	1780	1453
Diphtheria	54	68	185
Dog Bite.....	487	463	336
Epidemic Cerebrospinal Meningitis	10	10	8
German Measles.....	93	328	115
Gonorrhea	530	570	589
Lobar Pneumonia.....	566	285	416
Measles	483	650	1186
Mumps	1239	242	429
Scarlet Fever.....	1013	648	1107
Syphilis	437	383	417
Tuberculosis, Pulmonary.....	290	254	289
Tuberculosis, Other Forms.....	20	30	34
Typhoid Fever.....	5	11	20
Undulant Fever.....	6	—	—
Whooping Cough.....	292	651	736

*Based on the figures for the preceding 5 years

RARE DISEASES

Anterior poliomyelitis was reported from Belmont, 1, Beverly, 2, Boston, 3 Groton, 1 Lawrence, 1

Lynn, 4, Quincy, 1, Salem, 1, Saugus, 1, Shrewsbury, 1, Wareham, 1, Watertown, 1, Winchester, 1, Woburn, 1, Worcester, 1, total, 21

Anthrax was reported from Lynn, 1

Diphtheria was reported from Belmont, 1, Boston, 5, Brockton, 1, Chelsea, 1, Chicopee, 19, Dighton, 1, Fall River, 7, Franklin, 2, Lowell, 8, Melrose, 1, New Bedford, 2, Northbridge, 1, Revere, 1, Taunton, 2, Waltham, 1, Worcester, 1, total, 54

Dysentery (amebic) was reported from Medford, 1, New Bedford, 1, total, 2

Encephalitis lethargica was reported from Belmont, 1, Leominster, 1, total, 2

Epidemic cerebrospinal meningitis was reported from Leominster, 1, Newburyport, 1, Newton, 1, Springfield, 1, Winthrop, 1, Worcester, 5, total, 10

Malaria was reported from Boston, 1

Pellagra was reported from Beverly, 1, Boston, 1, total, 2

Septic sore throat was reported from Amherst, 1, Boston, 5, Chicopee, 2, Lynn, 1, Malden, 1, Stoneham, 1, Topsfield, 1, total, 12

Tetanus was reported from Boston, 1, Fitchburg, 1, Haverhill, 1, total, 3

Trachoma was reported from Bedford, 1, Somerville, 1, total, 2

Trichinosis was reported from Deerfield, 1, Plymouth, 1, total, 2

Undulant fever was reported from Holyoke, 1, Kingston, 1, Quincy, 1, Templeton, 1, Worcester, 2, total, 6

With 396 reported cases, diphtheria showed a very pleasing decrease of 37 per cent over last year's figure. Through November, diphtheria deaths were running 54 per cent below 1934.

Typhoid fever, with 112 reported cases, showed a decrease of 16 per cent over 1934.

There were 1,392 cases of anterior poliomyelitis reported in 1935 with 21 of these in December. Fifty seven deaths were reported through November as compared with 114 deaths in 1931 when there were 1,428 reported cases.

Although the figure for December, 10, is not remarkable, there were 83 cases of epidemic cerebrospinal meningitis in 1935 as compared with 66 in 1934, the increase being noted chiefly in May and October.

Lobar pneumonia was considerably above last December's figure and the yearly total was higher than for any year since 1929.

Scarlet fever has been running higher than 1934 since October and it would appear that the increased prevalence will be maintained through 1936.

Pulmonary tuberculosis for December was higher than 1934 as is the yearly total. The deaths, however, through November showed a considerable decrease over last year's figure.

Tuberculosis, other forms, whooping cough and measles were reported below December of 1934.

Mumps had its highest reported December incidence

German measles, while not remarkable for December had its highest reported total for any year 33,365 cases

Chickenpox There is nothing remarkable in the incidence of this disease

Undulant fever with 6 cases reported in December and 43 for the year had an increased incidence over 1934

The reporting of dog bites continues to run higher than last year

AN HONOR TO DR. JAMES B AYER

In recognition of the completion of twenty five years of teaching at the Harvard Medical School Dr James B Ayer James Jackson Putnam Clinical Professor of Neurology was honored recently at a dinner at the Tavern Club Boston

Dr C Macfie Campbell acted as toastmaster and speeches were delivered by Drs James H Means W Jason Mixer George L Walton Merrill Moore and Henry R Viets

CONNECTICUT STATE MEDICAL SOCIETY MAKES PROGRESS

At the session of the House of Delegates held in conjunction with the annual meeting of the Connecticut State Medical Society in May 1935 it was voted that the President of the Association shall on or before the 15th of June, 1935 appoint a Committee of eight members of which not more than one shall be resident in any County The function of this Committee shall be to inquire into the administration and activities of the Secretary of the Connecticut State Medical Society directing especial attention to

"1 The employment of a full time executive secretary for the Society

"2 The continuation of a volunteer secretary with a full time executive assistant.

3 The establishment of a permanent office for the Association in Hartford.

"4 Inquire into the expense likely to be incurred by such a program

"5 Suggested methods of financing the increase in the State Society budget incident to such program

6 Ways in which administrative activities of the various County Association Secretaries can be consolidated in a central State office

"This Committee shall report to the Council of the Connecticut State Medical Society not later than January 1 1936 presenting a résumé of its findings and recommendations for improved administration in the office of the Secretary"

This Committee on the Administration of the Office of the Secretary labored long and well It corresponded with the Secretary of every other State Medical Society in the Union and was surprised to learn that its own society members paid less in annual dues than the members of any other state society except two It also obtained first hand information from other societies where a full time secretary is successfully employed such as New Jersey In its report to the Council this Committee recommended "that a permanent executive secretary a male and a layman should be employed at a salary approximating \$4 000 and that a capable stenographic assistant at \$1 200 should be added to the office The Committee expressed itself as believing that a volunteer secretary with a full time executive assistant would be but a partial answer to the present and future needs of the Society It further recommended the establishment of a permanent office for the Society in Hartford on the grounds that the State Legislature State Medical Board of Examiners and State Department of Health are all located in Hartford and this city is centrally located geographically The Committee suggested a budget of \$12 000 to meet which the dues per capita would be increased from \$4 00 to \$8 00 per year and a saving realized by substituting a quarterly bulletin for the present expensive annual publication known as the Proceedings Furthermore the Committee suggested several ways in which the work of the component County Association Secretaries could be consolidated in a central State Society office

The Council of the State Medical Society was far from agreeing unanimously with the recommendations of the special Committee. Consequently a questionnaire was sent to every member requesting an expression of opinion as to whether a full time secretary or a part time member secretary with full time executive assistant was desired. There was some ambiguity in the wording of the questionnaire so that many of the members feel that the resulting ballot did not express the true opinion of all concerned The fact remains however that returns favored a part time member secretary with executive assistant.

The Council therefore, presented to the House of Delegates met in special session at New Haven on January 16 1936 the following resolutions all of which were adopted

- 1 The Council recommends to the House of Delegates that so much of a previous vote of the House of Delegates of an unknown date that authorizes the return to the County Associations of 10 per cent of the State dues collected by the County Associations be rescinded and that in the future the entire amount of the State dues collected by the County treasurers shall be delivered to the Treasurer of the Connecticut State Medical Society after the deduction of 5 per cent of the total amount collected which shall be the County Treasurer's recompense for his services in connection with the collection of the dues as at present.
- 2 The Council recommends to the House of Delegates that the publication of a single bound volume of the Transactions of the Connecticut State Medical Society be discontinued in the place thereof there shall be published a "Quarterly Bulletin on the Connecticut State Medical Society"

ciety" in the months of May, August, November and February of each year and distributed to all members of the Society. This Bulletin in addition to other material shall include—in the May issue, a directory of members of the Society, in the August issue, complete reports of business transacted by the House of Delegates at its annual meeting in May, and all reports presented before the House, in the November issue, comprehensive abstracts of all papers presented before the Connecticut Clinical Congress, in the February issue, such papers of conspicuous merit as may have been presented before the State Society or any County Association during the year.

Reprints of material published in the Bulletin will be supplied to authors or others on order at cost.

3 The Council recommends to the House of Delegates that an office for the Connecticut State Medical Society be established, and that in this office there shall be employed a competent stenographer on a full time basis at a sufficient salary to recompense a properly trained person, not to exceed \$1,500 per annum, and this office be provided with such furniture and equipment as may be required, cost thereof to be approved by the Council.

4 (a) The Council recommends to the House of Delegates that a member of the Society shall be nominated and elected at the Annual Meeting in 1936 and annually thereafter, to an office to be known as the Administrative Secretary of the Society. The function of this Secretary shall be as prescribed in Section 4, Chapter VI, of the By Laws, to carry on all administrative activities of the Society, and to keep its records and its roster, and to serve as the Secretary of the Council, of which he shall be a regular voting member as provided in Chapter VII, Section I, of the By Laws. This Secretary shall receive an honorarium of \$600 per annum, to be paid from the funds of the Society in twelve equal monthly installments of \$50 each.

(b) It is further recommended that two additional Secretaries shall be nominated by the Council and elected by the House of Delegates at its annual meeting in 1936 and annually thereafter. The first of these to be known as Legislative Secretary, whose function shall be to serve as the Secretary and executive officer of the Committee on Public Policy and Legislation, and to carry on such legislative activity as may be required, the Secretary to receive an honorarium of \$250 a year to be paid from the funds of the Society. The second of these additional secretaries shall be known as the Secretary on Scientific Work. His function shall be to serve as Chairman of the Committee on Scientific Work, to edit, publish, and distribute through the central office of the Society, the Quarterly Bulletin mentioned above, to arrange all scientific programs of the Society and to cooperate with

the various County Societies in the arrangement of their programs. This Secretary shall receive an annual honorarium of \$300 to be paid from the funds of the Society. The Legislative Secretary and the Secretary on Scientific Work shall not be voting members of the Council, but shall meet with that body from time to time and assist in its deliberations.

5 The Council further recommends that the Chairman of the Council, the Treasurer, and the three Secretaries of the Society shall be constituted a Budget Committee, that shall on or before the first of May each year, set up a budget for the Society which shall be submitted to the Council—sitting as the Finance Committee, as provided in Chapter VII, Section I, of the By Laws—for approval and submitted to the House of Delegates in its annual meeting for adoption.

6 The Council recommends to the House of Delegates that the dues collected from each member of the Connecticut State Medical Society for the year 1936 shall be \$5.00 and that the previous vote of the House of Delegates establishing the dues for 1936 at \$4.00 be rescinded.

By the adoption of these last six resolutions the Connecticut State Medical Society at its annual meeting on May 20-21, 1936, will create a better organized secretarial office than it now possesses and will proceed to publish a quarterly bulletin in place of its annual Proceedings. This surely is a step toward a more efficient organization and in the right direction.

CORRESPONDENCE

A HITHERTO (?) UNDESCRIBED SOURCE OF DERMATITIS VENENATA

Editor, *New England Journal of Medicine*,

I would like to bring to the attention of your readers an apparently hitherto unrecorded source of dermatitis venenata.

On December 9, 1935, there came to my office a high governmental official of a neighboring state with a large, oval, inflammatory area on the left side of his lower chest and upper abdomen. This area was approximately six inches by five in diameter and was red and dry almost to fissuring, resembling the eczema craquelé of the French, while the periphery was delicately peeling, simulating pityriasis rosea in that the free, loose edge of the desquamating scales was toward the center rather than toward the outer border.

The history revealed that five weeks previously a similar outbreak had occurred and subsequently died down and after an interval the present attack had developed. Itching and discomfort had preceded both of these eruptions and the home physician had recommended cold boric solution packs.

The patient uses two popular soaps, either of which, in the dryness of winter, can produce eczema craquelé on a susceptible skin, but not the unusual

type of desquamation observed in this instance. Boric acid can upset certain skins but even this possible etiological factor did not touch the patient's integument until after itching and discomfort had appeared.

Because of the boric acid complication no diagnosis was made and the patient was given a mild zinc oxide paste.

On December 11 a telephone message stated that the periphery of the patch had cleared that the disagreeable sensations had abated but that the centre showed no appreciable change. The addition of a zinc calamine glycerine and phenol lotion was recommended to precede the application of the paste.

On December 30 after a trip to Florida the patient returned to show two areas symmetrically placed over the lower chest and the upper abdomen each about 4" x 5" moist, dusky pinkish fading in intensity gradually toward the outer edge but without any signs of desquamation. No applications of any sort had been made so that this time we saw the rash in its virgin state.

The story since the previous visit was that on the second day in Florida the eruption began to fade and soon had fully vanished. The northern journey began on December 28 and on going to bed that night the earlier itching and discomfort had reappeared and the two present patches were evident.

Dermatitis artefacta could easily account for this extraordinary outburst but the upstanding manly nature of the patient excluded such a thought once and forever. The question of drugs was raised—especially phenolphthalein and the barbiturates although such a limited distribution seemed to make this surmise absurd and furthermore the taking of drugs was denied.

After further cogitation the patient was told that this phenomenon was easily explicable but that he himself was the one and not the physician who could solve the riddle because in all probability the outbreak was due to contact with some substance which could not be guessed by a stranger.

The man who was obviously intelligent, keen and interested was given time to think.

In a few moments the answer came. It seems that friends had advised the carrying of a gas cartridge in a pseudo-fountain pen because of threatening letters and the over-possible crank. The suggestion had been adopted just before the first cutaneous outbreak and when on duty the fake pen had been carried in an upper waistcoat pocket.

On reaching Florida, the first day had been cold and the northern clothes had been worn. Afterwards in the normal Florida weather sports clothes and evening clothes were used. For the homeward journey the winter suit was donned.

Recall the history. In the north, after a certain event, an eruption appeared and for the most part continued. In the south after one cold day certain clothes were discarded and the eruption disappeared. On the return journey the northern clothes were resumed and within twelve hours more or less the eruption had returned!

With these data in mind the waistcoat was exam-

ined. It gave no smell to the patient or to the inquisitive doctor but the upper waistcoat pockets fitted precisely over the two great plaques on the patient's torso! Questioning revealed that the gas gun was carried in either upper pocket from time to time. The cartridge was investigated but that also gave forth no appreciable odor or moisture.

Two separate attempts have been made to ascertain the name and nature of the gas in this cartridge but thus far the manufacturer or discharging company has ignored my letters of inquiry.

CHARLES J. WHITE, M.D.

250 Marlborough Street, Boston

P. S. A belated letter from the patient states that in all probability the tear gas present in the cartridge is chloroacetophenone.

A NEW BOOK ABOUT ARTISTS

Editor *New England Journal of Medicine*

May I call the attention of physicians interested in art to "Illyrian Spring" by Ann Bridge (Little Brown & Co., Boston, 1935).

This tale of the Dalmatian Coast and of the two artists who work there, well, I think, he of much interest to all physicians who paint, or to those others who like to see the efforts of their friends in artistic expression.

WM. FRANK COLES, M.D.

13 Monmouth Court,
Brookline, Mass.

RECENT DEATH

MOAKLEY—ROBERT CLEMENT MOAKLEY, M.D., of Lexington, Massachusetts, died at his home January 30, 1936. He was born in Lexington April 15, 1877, the son of James and Mary (Downey) Moakley. He graduated from the College of Physicians and Surgeons (Boston) in 1915.

Two brothers, John, of Lexington and William L. Moakley of Watertown and four sisters, Mrs. John E. Burke of Lynn, Mrs. Florian D. Record of Quincy, Mrs. Cornelius D. Gallagher of Lexington and Mrs. Patrick H. Mahoney of Wrentham survive him.

NOTICES

ANNOUNCEMENT

JOSEPH LENTINE, M.D. announces the opening of his office at 500 Park Drive, Boston.

REMOVAL

EDWARD ALLEN EDWARDS, M.D., announces the removal of his office to 330 Dartmouth Street, at Beacon Street, Boston.

AWARDS

The New England Society of Psychiatry, at its next Spring meeting, will make two awards, one of \$50.00 and one of \$25.00 to the writer (or writers) of the best papers completed or published during the calendar year of 1935 embodying research in

psychiatry by a younger worker (or workers) Physicians, psychologists, social workers, or others are eligible Membership in the Society is not a requisite

Authors who present articles for consideration should make arrangements with the publishers of their papers to preserve the plates, until such time as the awards are made, from which reprints could be made and furnished to the members by the Society

Writers who have once received an Award are not again eligible Seasoned writers, senior physicians, or heads of departments in which there are junior workers, while not inevitably excluded, will not generally be regarded as eligible for the Awards

The work on which the papers are based should preferably have been done in New England or by workers now living in New England

The papers will be examined by a Committee of three members who are accustomed to reviewing papers, and by the Executive Committee of the Society They will be judged on the basis of their scientific quality

Copies of articles or marked copies of journals in which the articles appeared should be sent before March 1, 1936, to the Secretary of the Society

Superintendents of institutions, public or private, for the care of mental patients in New England, also Deans of colleges and universities maintaining medical schools or departments of psychology are requested to post this notice, and to send to the Secretary a list of such papers published as they think entitled to be considered for the Awards

HARLAN J PAINE, MD, *Secretary*

North Grafton, Mass

MEDICAL CLINIC AND STAFF ROUNDS AT THE PETER BENT BRIGHAM HOSPITAL

At 3 30 PM on Thursday, February 13, in the Amphitheatre of the Peter Bent Brigham Hospital, Dr Henry A. Christian, Physician in Chief, Hersey Professor of the Theory and Practice of Physic in the Harvard Medical School, will give a medical clinic To it are cordially invited practitioners and medical students

On Saturdays in the wards of the Peter Bent Brigham Hospital, from 10 to 12, staff rounds will be conducted by Dr Christian

REPORTS AND NOTICES OF MEETINGS

WILLIAM HARVEY MEDICAL SOCIETY

The William Harvey Medical Society met at the Beth Israel Hospital Dec 13, 1935, Dr Nathan Sidel presiding Dr Martin Dawson, assistant professor of medicine at Columbia University School of Medicine, spoke on "Rheumatoid and Osteo-Arthritis"

Chronic arthritis is the greatest single cause of disability in this part of the world, causing the loss of seven and a half million weeks' work in the

United States each year One of every five patients seeking medical advice does so because of ailments attributable to chronic arthritis The disease is divisible into two main classes rheumatoid arthritis and osteo-arthritis, each a separate disease with different etiology, different pathology, and different clinical course

Rheumatoid arthritis is characterized by a chronic progressive involvement of articular structures Eighty per cent of the cases develop between the ages of twenty and fifty years The disease is three times more prevalent in females than in males Its manifestations are protean, but there is no reason for separating it into such categories as "atrophic", or "infectious" types. Marie Strumpell's disease and Still's disease are also merely clinical manifestations of the same underlying pathological process

The etiology is unknown, although it is probably a specific infectious disease, and circumstantial evidence has pointed to hemolytic streptococcus infection as the probable causative agent The geographical distribution of the disease is similar to that of rheumatic fever, the incidence being high in temperate climates, and low in southern and subtropical regions The seasonal incidence of onset is the same as that of hemolytic streptococcus infections, the peak being from February to May Serum from patients with rheumatoid arthritis agglutinates certain strains of streptococci in dilutions as high as one part in one hundred and sixty Such agglutination occurs only in patients with diseases of known streptococcus etiology Only certain strains of streptococci belonging to the alpha group (the group responsible for most human infections) are so agglutinated In spite of this evidence, streptococci are not recoverable from either the joints or the blood stream in cases of the disease The concept of allergy must be utilized to explain the observant relationships

Dr Dawson warned against the unreserved acceptance of the theory of focal infection Tonsillar infection may be of importance, but the importance of prostatic and dental infection as causative of rheumatoid arthritis has been over emphasized

Pathologically rheumatoid arthritis begins in the periarticular tissues There follows the formation of a connective tissue pannus over the articular cartilage, which subsequently results in the destruction of the cartilage The focal collections of small round cells in the synovia are as characteristic of rheumatoid arthritis as the tubercle is of tuberculosis X ray studies reveal generalized osteoporosis, and a swelling of the periarticular tissues of the involved joints Although disturbances of metabolism occur in some instances, none have been consistently demonstrated Constitutional manifestations such as fever and accelerated sedimentation rate are frequently observed The relationship between rheumatoid arthritis and rheumatic fever, although interesting, has not been proved

Osteo-arthritis must be considered as a degenerative disease, due to the wear and tear of many years' use, or to abnormal transmission to one particular joint. It is a disease of old age, and infectious processes have no part in its etiology. Pathological changes are confined to local areas and there is no general systemic involvement such as is found in rheumatoid arthritis. There is a central degeneration of the articular cartilage, with subsequent increased strain on the periphery and resultant hypertrophic spur formation. There is little or no change in the synovia. X-rays reveal spur formation and do not show the osteoporosis characteristic of rheumatoid arthritis.

Osteo-arthritis is insidious in onset, and may not attract the attention of the patient until fairly far advanced. The terminal phalangeal joint and the knee joints are those most frequently involved. They are "guarried" in appearance in contradistinction to the fusiform swelling observed in rheumatoid arthritic joints. Systemic symptoms are absent and the sedimentation rate is normal or only slightly elevated.

The prognosis in rheumatoid arthritis must be guarded. Twenty to 25 per cent grow progressively worse. 50 per cent show improvement and 5 per cent recover completely. Since 70 to 80 per cent of cases improve without treatment, conclusions as to the efficacy of any particular form or therapy must be carefully considered. Osteo-arthritis is a progressive degeneration and recovery cannot be expected.

In the treatment of rheumatoid arthritis rest is as important as it is in the treatment of tuberculosis. Daily motion of the affected joints must be maintained, however but not to an extent sufficient to tax the physical ability of the patient. Physiotherapy is of value in many cases and local treatment to prevent the development of deformities or to correct those already existent, is of importance. Dr. Dawson condemned the prescription of unseasoned diets, and recommended high vitamin high caloric feedings. There is little evidence to substantiate the theory of focal infection as the exciting agent, except for tonsillar infection. Obviously infected tonsils should be removed. Trial of numerous vaccines has failed to show any definite benefit from this form of therapy. Foreign protein shock may bring about temporary but not permanent improvement. Injections of colloidal metals have not been of value. Aspirin and codein should be used freely to relieve discomfort.

The treatment of osteo-arthritis consists in attempting to prevent the progression of the disease since nothing can be done to restore degenerated cartilage. Weight reduction and physiotherapy are often of value in arresting the rapidity of the degenerative process. Special diets, vaccines, removal of foci of infection and drug therapy are not indicated.

BOSTON SOCIETY OF BIOLOGISTS

The December meeting of the Boston Society of Biologists was held on December 18 at the Harvard Biological Laboratories in Cambridge. The first paper of the evening was on "Certain Metabolic Effects of the Pituitary" by Dr. Joseph C. Aub. It has been known for some time that if the pituitary is removed an atrophy of the parathyroid results, while if there is hypertrophy of the pituitary gland the parathyroid is overactive. In the lead there is a low blood calcium after hypophysectomy there is no abnormality in the calcium metabolism of acromegals.

Dr. Aub studied the calcium metabolism in a typical case of basophilic adenoma. This patient, who had been a normal girl at the age of ten began to gain weight rapidly at about the age of twelve, became sluggish mentally and amenorrhea followed. Examination showed a considerable amount of hirsutism, purplish trophic etriae and by x-ray a definite decalcification of the bones with a loss of two inches in height. The blood pressure was 150/110 and there was considerable prolapse in the urine. By putting her on a low calcium diet, containing 100 milligrams of calcium a day this patient's calcium metabolism was studied before and after treatment. The normal person on this diet excretes 150 milligrams of calcium in the urine and 450 milligrams in the feces. This patient before treatment excreted five times the normal amount of calcium in her urine and feces. After x-ray treatment the calcium output became lower than normal, the blood pressure reached the normal level, she lost weight, the catamenia became normal and her bones became normally calcified again.

A study of the magnesium showed no abnormality before or after treatment and the blood calcium was at all times within normal limits. The basal metabolism rate which before treatment had been minus 34 rose to the usual level and her sugar tolerance which had shown a characteristic diabetic curve also returned to normal.

The second paper was on "Area in Vision and Theories of Retinal Interaction" by Dr. George Wald. As the area of the visual field is increased all the functions of the eye improve. The relationship between the area of the field and the values of these various functions were considered from both an experimental and mathematical point of view. Although it was previously found that the product of the area times the threshold is roughly equal to a constant in the case of foveal fields, and that the square root of the area times the threshold is approximately equal to another constant in the case of peripheral fields, no general equation has previously been derived to account for this relationship in all parts of the field. Dr. Wald has carefully worked out such an equation and has shown that the calculated figures closely coincide.

Obviously this report is chiefly one of results in congestive failure. The paucity of angina cases comes from no prejudice against the procedure for them, but simply from the fact that the angina patients seen here have either had inadequate medical treatment, or have been too seriously sick for operation, or have been given alcohol nerve injections by preference.

This report includes no patient with thyrotoxicosis. In all instances the ablated thyroid gland was normal histologically.

III Methods of Procedure

Patients seen in the Out Patient Department whom it was felt might benefit from total thyroidectomy have been sent into the medical service for further study. There, after complete workup, they have been seen by members of the cardiac and thyroid clinics, and of the surgical service who have given their opinions as to the feasibility of operation.

On the day of operation, the patients have been transferred to the surgical service. The operations have been performed by one of three surgeons, Dr Arthur W Allen, Dr Edward D Churchill or Dr Richard H Miller. The patients have in some cases been discharged directly from the surgical ward, and in other cases have returned to the medical ward for further convalescence before discharge. In all instances the medical men have followed the patients in the surgical wards, and every effort for cooperation between the two services has been made.

Following discharge from the hospital, patients have been followed at regular intervals by one of us (R J C) in the metabolism laboratory. He has had the constant assistance of various members of the thyroid and cardiac clinics.

Six of the patients reported in this series are private ones operated on in the Baker Memorial or Phillips House. They have been selected and followed in much the same way as the ward patients, except that the follow-ups have been made by their own physicians. We are indebted to Dr P D White, Dr H B Sprague and Dr John Cass for permission to include their patients in this report.

The evaluation of results presented here has been made following considerable deliberation. It takes into account the opinions of members of the patient's family in some cases, in some cases that of the family physician or the patient's private consultant, but finally it represents the opinion of the writers who have seen these cases through their course. Criticism of selection and evaluation of results have also been checked over, on the basis of case summaries, by members of another hospital clinic carrying on the same work. The agreement as to classification of patients has been surprisingly close.

IV Selection of Cases

The proper selection of cases for total thyroidectomy presents perhaps the greatest and the most important problem of all. In the early months we tried to be guided largely by the previous short experience of those in the pioneer clinics. That we have made several errors in judgment will be apparent on inspection of the data. We have continued to learn from our own experience and from that of others. On the basis of this experience at the present time we would list the following as cases in which operation is definitely contraindicated.

- 1 Patients that have not been given the benefit of entirely adequate medical treatment over a sufficient period of time for full evaluation of its results.
- 2 Patients showing a rapid progression in spite of adequate medical care. A case such as No 1 (see below) with gross breaks in compensation at yearly intervals may be considered as slowly progressive. Cases such as No 17 and No 21 with second breaks in compensation within three months of the first in spite of rest and adequate care are too rapidly progressive. Cases of syphilitic heart disease as No 7 are per se too rapid in their downward course.
- 3 Patients with such severe heart disease that they are unable to establish and maintain compensation on digitalis and bed rest. This eliminates cases with persistent ascites or hydrothorax as No 6.
- 4 Patients with high grade mitral stenosis or other mechanical obstruction giving rise to high venous pressure sustained after compensation has been restored.
- 5 Patients with a low preoperative basal metabolism. Generally minus fifteen is considered to be the borderline, but as may be seen in case No 16, an angina with a good result, the preoperative level was minus seventeen.
- 6 Patients with chronic pulmonary disease of any type. The possibility of pulmonary infarction or thrombosis in cardiac patients as a cause for rapid failure in spite of adequate treatment has recently been emphasized², and when it has been suspected should certainly contraindicate operation. See case No 21.
- 7 Patients with severe nephritis — low P S P test or high N P N.
- 8 Patients with malignant or severe hypertension, especially if associated with generalized arteriosclerosis. See cases No 9 and No 11.
- 9 Patients with active rheumatic infection, bacterial endocarditis, or other concomitant infection.

Osteo-arthritis must be considered as a degenerative disease due to the wear and tear of many years use, or to abnormal trauma to one particular joint. It is a disease of old age and infectious processes have no part in its etiology. Pathological changes are confined to local areas, and there is no general systemic involvement such as is found in rheumatoid arthritis. There is a central degeneration of the articular cartilage with subsequent increased strain on the periphery and resultant hypertrophic spur formation. There is little or no change in the synovia. X-rays reveal spur formation and do not show the osteoporosis characteristic of rheumatoid arthritis.

Osteo-arthritis is insidious in onset, and may not attract the attention of the patient until fairly far advanced. The terminal phalangeal of the wrist and the knee joints are those most frequently involved. They are gnarled in appearance, in contradistinction to the fusiform swelling observed in rheumatoid arthritic joints. Systemic symptoms are absent and the sedimentation rate is normal or only slightly elevated.

The prognosis in rheumatoid arthritis must be guarded. Twenty to 25 per cent grow progressively worse. 50 per cent show improvement and 75 per cent recover completely. Since 70 to 80 per cent of cases improve without treatment, conclusions as to the efficacy of any particular form of therapy must be carefully considered. Osteo-arthritis is a progressive degeneration and recovery cannot be expected.

In the treatment of rheumatoid arthritis, rest is as important as it is in the treatment of tuberculosis. Daily motion of the affected joints must be maintained, however, but not to an extent sufficient to tax the physical ability of the patient. Physiotherapy is of value in many cases, and local treatment to prevent the development of deformities, or to correct those already existent, is of importance. Dr. Dawson condemned the prescription of unsound diets, and recommended high vitamin high caloric feedings. There is little evidence to substantiate the theory of focal infection as the exciting agent, except for tonsillar infection. Obviously infected tonsils should be removed. Trial of numerous vaccines has failed to show any definite benefit from this form of therapy. Foreign protein shock may bring about temporary but not permanent improvement. Injections of colloidal metals have not been of value. Aspirin and codein should be used freely to relieve discomfort.

The treatment of osteo-arthritis consists in attempting to prevent the progression of the disease since nothing can be done to restore degenerated cartilage. Weight reduction and physiotherapy are often of value in arresting the rapidity of the degenerative process. Special diets, vaccines, removal of foci of infection and drug therapy are not indicated.

BOSTON SOCIETY OF BIOLOGISTS

The December meeting of the Boston Society of Biologists was held on December 18 at the Harvard Biological Laboratories in Cambridge. The first paper of the evening was on "Certain Metabolic Effects of the Pituitary" by Dr. Joseph C. Aub. It has been known for some time that if the pituitary is removed an atrophy of the parathyroid results, while if there is hypertrophy of the pituitary gland the parathyroid is overactive. In the toad there is a low blood calcium after hypophysectomy; there is no abnormality in the calcium metabolism of acromegalics.

Dr. Aub studied the calcium metabolism in a typical case of basophilic adenoma. The patient, who had been a normal girl at the age of ten, began to gain weight rapidly at about the age of twelve, became sluggish mentally and amenorrhea followed. Examination showed a considerable amount of hirsutism, purplish atrophic striae and by x-ray a definite decalcification of the bones with a loss of two inches in height. The blood pressure was 150/110 and there was considerable prolapse in the urine. By putting her on a low calcium diet, containing 100 milligrams of calcium a day, this patient's calcium metabolism was studied before and after treatment. The normal person on this diet excretes 150 milligrams of calcium in the urine and 450 milligrams in the feces. This patient before treatment excreted five times the normal amount of calcium in her urine and feces. After x-ray treatment the calcium output became lower than normal; the blood pressure reached the normal level, she lost weight, the catamenia became normal and her bones became normally calcified again.

A study of the magnesium showed no abnormality before or after treatment, and the blood calcium was at all times within normal limits. The basal metabolism rate which before treatment had been minus 34 rose to the usual level and her sugar tolerance which had shown a characteristic diabetic curve also returned to normal.

The second paper was on "Area in Vision and Theories of Retinal Interaction" by Dr. George Waid. As the area of the visual field is increased all the functions of the eye improve. The relationship between the area of the field and the values of these various functions were considered from both an experimental and mathematical point of view. Although it was previously found that the product of the area times the threshold is roughly equal to a constant in the case of foveal fields, and that the square root of the area times the threshold is approximately equal to another constant in the case of peripheral fields, no general equation has previously been derived to account for this relationship in all parts of the field. Dr. Waid has carefully worked out such an equation and has shown that the calculated figures closely coincide

with the experimental. He concludes that there is no retinal interaction and that the number of elements involved constitute the only important factor.

The last paper was delivered by Vincent E Morgan on the "Study of the Solubility of Muscle Hemoglobin." Muscle hemoglobin, or myoglobin, was first crystallized in 1932 when its preparation from horse heart muscle was described. The fact that it is much more soluble in certain phosphate solutions than is blood hemoglobin, has been used in the separation of these two forms of hemoglobin. By carefully controlling the concentration of the phosphate solution, Dr Morgan has been able to separate these two hemoglobins so that in his preparation there is only one part of blood hemoglobin to one million of myoglobin.

ESSEX SOUTH DISTRICT MEDICAL SOCIETY

The regular meeting of the Essex South District Medical Society was held at the Danvers State Hospital, Hathorne, on January 8, 1936.

Dr Bonner and members of his staff conducted the Society through the Wards. After the ward visit an interesting clinic was held and the following papers were read by Staff members:

The Use of Estrogenic Substances in Involution Psychosis, Dr Melvin Goodman.

The Effect of Physical Illness on Some Cases of Mental Disease, Dr Salvador Jacobs.

Some Usual and Unusual Methods of Suicidal Attempts in Mental Cases, Dr Edgar C Yerbury.

About seventy members were in attendance at dinner which was followed by a most instructive talk on:

Endocrine Factors in Personality by Dr R G Hoskins, Director of Research at Worcester State Hospital and Associate in Research at Harvard Medical School.

N P BREED, M D, *Reporter*

BOSTON PATHOLOGICAL SOCIETY

The stated meeting of the Boston Pathological Society was held in the Pathology Laboratory of the Children's Hospital on Monday evening, January 13, 1936. Dr Monroe J Schlesinger, President of the Society, presided.

The first part of the evening was devoted to an exhibition and discussion of gross and microscopic pathological specimens contributed by members of the society from their laboratories.

Following this, there was an address by Dr J Stewart Rooney on some aspects of legal medicine. Dr Rooney began by giving his viewpoint on the doctor as a witness and mentioned the many pitfalls, as well as interesting experiences, a physician encounters in the courtroom. He described briefly the differences between the Medical Examiner and the Coroner systems. He feels that the former is more satisfactory because a Medical Examiner does

not have so much judicial power as a Coroner does, and therefore, has not the individual right to decide legal questions. Dr Rooney then showed lantern slides which very graphically illustrated the many problems which present themselves in the doctor's study of crime.

Refreshments were served after the meeting and final adjournment was about ten thirty.

NEW ENGLAND DERMATOLOGICAL SOCIETY

The next meeting of the New England Dermatological Society will be held on Wednesday, February 12, at 3 P M, at the Massachusetts General Hospital.
J HARPER BLAISDELL, M D, *Secretary*

THE SOUTH END MEDICAL CLUB

The next regular meeting of the South End Medical Club will be held at the office of the Boston Tuberculosis Association, 554 Columbus Avenue, Boston, on Tuesday, February 18, at 12 noon. The speaker will be James H Means, M D, Professor of Clinical Medicine, Harvard Medical School, Chief of Medical Services, Massachusetts General Hospital. His subject will be "Remarks on the Use of Thyroid." All physicians are cordially invited to attend the meeting. The usual luncheon will be served.

WORCESTER DISTRICT MEDICAL SOCIETY

WORCESTER STATE HOSPITAL
FEBRUARY 12, 1936

PROGRAM

Dinner 6 30 P M

Business Meeting 8 00 P M

PAPERS

Legal Commitments William A. Bryan, M D, Superintendent, Worcester State Hospital.

The Effect of Duodenal Extracts in Diabetes Mellitus J M Looney, M D, Director, Laboratories Worcester State Hospital, and W E Glass, M D, Chief Physician, Medical and Surgical Service, Worcester State Hospital.

Epilepsy, Bromidism and Brain Tumor Benjamin Simon, M D, Assistant Physician Worcester State Hospital, and Morris Yorshis, M D, Clinical Director, Worcester State Hospital.

TRUDEAU MEDICAL SOCIETY

A whole-day meeting of the Trudeau Medical Society will be held on February 11.

Morning Program—Clinics 9 12

Thoracic Dry Clinic at the Massachusetts General Hospital—Dr Donald King.

Operative Clinic at the Peter Bent Brigham Hospital—Dr Harian Newton.

Operative Clinic at the Deaconess Hospital—Dr Richard Overholt.

1 P M Luncheon at the Essex County Sanatorium, Middleton, Mass.

- 2 P.M.-4 P.M. Round Table Conference of cases presented by the staff of Essex County Sanatorium
- 6 30 P.M. Dinner tendered to Drs. Max Pinner and Pol N. Coryllos—at the Harvard Club Boston.
- 8 15 P.M. Auditorium—Beth Israel Hospital. The speaker will be Dr. Max Pinner, Assistant Editor of the *Review of Tuberculosis* who will talk on "The Diagnostic and Prognostic Significance of Positive and Negative Sputum." The paper will be discussed by Dr. Pol N. Coryllos, Thoracic Surgeon of the Sea View Hospital, New York.

HARVARD MEDICAL SOCIETY

The next meeting of the Harvard Medical Society will be held in the Peter Bent Brigham Hospital Amphitheatre (Shattuck Street Entrance) Tuesday evening February 11 at 8 15 P.M.

PROGRAM

Presentation of Cases

The Effect of Hypophysectomy and Adrenalectomy upon Experimental Diabetes in the Cat. By Dr. C. N. H. Long, University of Pennsylvania, Philadelphia, Pennsylvania.

Medical students and physicians are cordially invited to attend.

MARSHALL N. FULTON, M.D., Secretary

WILLIAM HARVEY SOCIETY

The next meeting of the William Harvey Society will be held Friday February 14 in the Auditorium of the Beth Israel Hospital, Boston at 8 00 P.M.

PROGRAM

Speaker: Dr. L. Emmett Holt, Associate Professor of Pediatrics, Johns Hopkins Medical School. Subject: Significance of Fats in Nutrition. Chairman: Dr. Elmer Barron, Professor of Pediatrics, Tufts College Medical School.

SOCIETY MEETINGS, CONGRESSES AND CONFERENCES

CALENDAR OF BOSTON DISTRICT FOR THE WEEK BEGINNING MONDAY FEBRUARY 10 1936

Tuesday February 11—

- 9-10 A.M. Boston Dispensary, 55 Bennett Street, Boston. Recognition of the Early Psychoses. Dr. A. Warren Stearns.
- 10 P.M. Pediatric Ward Visit, Massachusetts Eye and Ear Infirmary.
- 8 15 P.M. Harvard Medical Society, Peter Bent Brigham Hospital Amphitheatre (Shattuck Street Entrance).
- 8 15 P.M. The Trudeau Society, Auditorium of the Beth Israel Hospital, Boston.

Wednesday February 12—

- 9 10 A.M. Boston Dispensary, 55 Bennett Street, Boston. Mistakes Made in the Diagnosis and Treatment of Syphilis. Dr. Francis Thurman.
- 11 12 M. Clinical Pathological Conference, Children's Hospital.
- 2 P.M. New England Dermatological Society, Massachusetts General Hospital.

Thursday February 13—

- 8 30 9 30 A.M. Clinic, Surgical and Orthopedic Staffs of Children's Hospital at the Children's Hospital.
- *9 10 A.M. Boston Dispensary, 55 Bennett Street, Boston. Social Service Case Presentation, Miss Edith Canterbury.
- *2 30 P.M. Medical Clinic at the Peter Bent Brigham Hospital.

Friday February 14—

- 9 10 A.M. Boston Dispensary, 55 Bennett Street, Boston. Pituitary-Tropic Studies. Dr. Saul Herik.
- 12 M. Massachusetts General Hospital. Clinical Meeting of the Staff of the Children's Medical Service, Elber House.
- 8 P.M. William Harvey Society, Auditorium of Beth Israel Hospital, Boston.

Saturday February 15—

- *9 10 A.M. Boston Dispensary, 55 Bennett Street, Boston. Presentation of Ward Cases. Dr. H. C. Gordinier.
- *10 12. Staff rounds at the Peter Bent Brigham Hospital.

Sunday February 16—

- 4 P.M. Free Public Lecture, Harvard Medical School, Building D, Longwood Avenue. The Prospect of Keeping a Good Heart. Dr. W. H. Robey.

Open to the medical profession.
Open to Fellows of the Massachusetts Medical Society.

February 6—Faulkner Hospital Clinical Meeting at 5 P.M.

February 11—Harvard Medical Society. See notice elsewhere on this page.

February 11—The Trudeau Society. See page 74.

February 12—New England Dermatological Society. See page 74.

February 13—Medical Clinic, Peter Bent Brigham Hospital. See page 373.

February 14—William Harvey Society. See notice elsewhere on this page.

February 15—The South End Medical Club. See page 74.

February 24—Springfield Medical Association, 8 30 P.M. at the rooms of the Springfield Academy of Medicine, 40 Maple Street.

February 24 to May 16—International Medical Postgraduate Courses in Berlin. See page 1211 issue of December 13, 1935.

March 2—The American College of Physicians. See page 31, issue of January 7.

April 20-24—A Postgraduate Institute in Philadelphia. See page 23, issue of January 21.

June 15-19—The Executive Board of the Catholic Hospital Association will meet at the Fifth Regiment Armory, Baltimore, Md.

September 1936—First International Conference on Fever Therapy. See page 1225 issue of December 4, 1935.

October 19 23—Clinical Congress of the American College of Surgeons. See page 120 issue of January 22.

DISTRICT MEDICAL SOCIETIES

ESSEX SOUTH DISTRICT MEDICAL SOCIETY

February 12—Wednesday. Addison Gilbert Hospital, Gloucester. Clinic 8 P.M. Dinner 7 P.M. Speaker and subject to be announced later.

March 4—Wednesday. Lynn Hospital, Clinic 5 P.M. Dinner 7 P.M. Speaker Dr. Timothy Leary. Subject: Arteriosclerosis.

April 1—Wednesday. Essex Sanatorium, Middleton. Clinic 8 P.M. Dinner 7 P.M. Speaker: Dr. Richard H. Overholser of the Lohay Clinic. Subject: Chest Surgery.

May 7—Thursday. Censor Meeting.

May 13—Wednesday. Annual Meeting. Salem Country Club. Dinner at 7 P.M. Speaker: Dr. Paul White. Subject to be announced later.

R. E. STONE, M.D., Secretary
11 Lothrop Boulevard, Beverly.

FRANKLIN DISTRICT MEDICAL SOCIETY

Meetings are held on the second Tuesday of March and May at the Weldon Hotel, Grandfield at 11 A.M.

TOTAL THYROIDECTOMY FOR HEART DISEASE*

Experiences With Twenty One Patients at
The Massachusetts General Hospital

BY RICHARD J. CLARK, M.D.,† JAMES H. MEANE, M.D.† AND HOWARD B. SPRAGUE, M.D.†

I Introduction

WHEN a new form of therapeutics is invented and seems to rest on sound theoretical considerations and is backed up by encouraging results in the hands of the inventors it is very desirable that it be given adequate and careful trial by other professional groups.

The proposal, by Blumgart, Levine and Berlin in 1933, of total ablation of the normal thyroid for the relief of heart disease seemed to us to rest on a reasonable theoretical basis. We also had the opportunity, very early in the history of this form of treatment, to examine the patients at the Beth Israel Hospital who had been subjected to the operation in question and were very favorably impressed with their seeming improvement.

The theory underlying this new practice was elemental in its simplicity. If the heart has so much work to do that it becomes inadequate give it less to do and perhaps it will again become adequate. Or in the case of angina pectoris, if the coronaries are not capacious enough to allow the blood the myocardium's metabolism requires to pass with ease, decrease the myocardium's oxygen requirement and the coronaries may then become relatively adequate. In both cases it is an adjustment of demand for function to supply of function, that is to say, functional capacity on the one hand of the heart muscle as a pump, on the other of the coronaries as passageways.

There was also considerable past experience which lent support to these theories. Patients with myxedema have long been known to develop angina pectoris occasionally when given thyroid. Thyrotoxic patients with congestive heart failure have regained cardio compensation when their thyrotoxicosis has been abolished. One is justified in relating these phenomena to shifts in the level of metabolism.

Previously, detailed studies of the heart in

forty eight myxedema patients had been made at this clinic. We showed that while cardiac enlargement was frequently present, decreasing under thyroid medication, and while electrocardiographic changes were always present there were no patients with signs or symptoms of congestive failure attributable to the "myxedema heart".

For these various reasons it was decided in 1933 to make a trial of the therapeutic method of Blumgart, Levine and Berlin at the Massachusetts General Hospital. We considered that our approach should be primarily from the viewpoint of clinical rather than laboratory investigation. We wished to determine for ourselves the practicability and usefulness of the method for the treatment of cardiac patients in a large general hospital without unduly elaborate special service set-ups or without special technicians or nurses working on the problem, and without special added expense.

We shall first report our findings and then attempt to evaluate them.

II Patients Studied

This report is based on a study of twenty one patients operated on between July 1933 and May 1935. The three patients operated on in 1935 are now dead. The last patient to be operated on who is still surviving, was done in August, 1934 and has been followed for fourteen months. Therefore all patients have been observed for a sufficient period of time to make a reasonable evaluation of results. An etiological summary of the cases is presented in table I.

TABLE I

21 Cases.	15 Ward Patients	6 Private Patients
19 Cases of Congestive Failure		
12 Rheumatic Heart Disease		
4 Rheumatic and Hypertensive Heart Disease		
2 Hypertensive Heart Disease		
1 Syphilitic Heart Disease		
2 Cases of Angina Pectoris		
1 Pure Angina.		
1 Hypertensive Heart Disease with Angina and Failure.		
10 Males.	11 Females.	
Ages 27 to 67	Average 42½ years.	

From the Thyroid and Cardio Clinics of the Massachusetts General Hospital.

†Clark, Richard J.—Assistant in Medicine, Massachusetts General Hospital. Means, James H.—Professor of Clinical Medicine, Harvard University Medical School. Sprague, Howard B.—Assistant Physician, Massachusetts General Hospital. For records and addresses of authors see "This Week's Issue" page 328.

Obviously this report is chiefly one of results in congestive failure. The paucity of angina cases comes from no prejudice against the procedure for them, but simply from the fact that the angina patients seen here have either had inadequate medical treatment, or have been too seriously sick for operation, or have been given alcohol nerve injections by preference.

This report includes no patient with thyrotoxicosis. In all instances the ablated thyroid gland was normal histologically.

III Methods of Procedure

Patients seen in the Out Patient Department whom it was felt might benefit from total thyroidectomy have been sent into the medical service for further study. There, after complete workup, they have been seen by members of the cardiac and thyroid clinics, and of the surgical service who have given their opinions as to the feasibility of operation.

On the day of operation, the patients have been transferred to the surgical service. The operations have been performed by one of three surgeons, Dr Arthur W Allen, Dr Edward D Churchill or Dr Richard H Miller. The patients have in some cases been discharged directly from the surgical ward, and in other cases have returned to the medical ward for further convalescence before discharge. In all instances the medical men have followed the patients in the surgical wards, and every effort for cooperation between the two services has been made.

Following discharge from the hospital, patients have been followed at regular intervals by one of us (R J C) in the metabolism laboratory. He has had the constant assistance of various members of the thyroid and cardiac clinics.

Six of the patients reported in this series are private ones operated on in the Baker Memorial or Phillips House. They have been selected and followed in much the same way as the ward patients, except that the follow-ups have been made by their own physicians. We are indebted to Dr P D White, Dr H B Sprague and Dr John Cass for permission to include their patients in this report.

The evaluation of results presented here has been made following considerable deliberation. It takes into account the opinions of members of the patient's family in some cases, in some cases that of the family physician or the patient's private consultant, but finally it represents the opinion of the writers who have seen these cases through their course. Criticism of selection and evaluation of results have also been checked over, on the basis of case summaries, by members of another hospital clinic carrying on the same work. The agreement as to classification of patients has been surprisingly close.

IV Selection of Cases

The proper selection of cases for total thyroidectomy presents perhaps the greatest and the most important problem of all. In the early months we tried to be guided largely by the previous short experience of those in the pioneer clinics. That we have made several errors in judgment will be apparent on inspection of the data. We have continued to learn from our own experience and from that of others. On the basis of this experience at the present time we would list the following as cases in which operation is definitely contraindicated:

- 1 Patients that have not been given the benefit of entirely adequate medical treatment over a sufficient period of time for full evaluation of its results.
- 2 Patients showing a rapid progression in spite of adequate medical care. A case such as No 1 (see below) with gross breaks in compensation at yearly intervals may be considered as slowly progressive. Cases such as No 17 and No 21 with second breaks in compensation within three months of the first in spite of rest and adequate care are too rapidly progressive. Cases of syphilitic heart disease as No 7 are per se too rapid in their downward course.
- 3 Patients with such severe heart disease that they are unable to establish and maintain compensation on digitalis and bed rest. This eliminates cases with persistent ascites or hydrothorax as No 6.
- 4 Patients with high grade mitral stenosis or other mechanical obstruction giving rise to high venous pressure sustained after compensation has been restored.
- 5 Patients with a low preoperative basal metabolism. Generally minus fifteen is considered to be the borderline, but as may be seen in case No 16, an angina with a good result, the preoperative level was minus seventeen.
- 6 Patients with chronic pulmonary disease of any type. The possibility of pulmonary infarction or thrombosis in cardiac patients as a cause for rapid failure in spite of adequate treatment has recently been emphasized⁵, and when it has been suspected should certainly contraindicate operation. See case No 21.
- 7 Patients with severe nephritis — low PSP test or high NPN.
- 8 Patients with malignant or severe hypertension, especially if associated with generalized arteriosclerosis. See cases No 9 and No 11.
- 9 Patients with active rheumatic infection, bacterial endocarditis, or other concomitant infection.

10 Potents with recent coronary thrombosis, within six months

11 Potents with status angiosus

Intractable heart disease, incapacitating the patient or making him too uncomfortable in spite of adequately and fully prescribed care not eliminated by one of the above contraindications, may be considered to constitute an indication for operation.

It has been our experience that the distressing symptoms of precordial ache, paroxysmal dyspnea and palpitation have been the symptoms most readily relieved. The fatigue and weakness of the cardiac rarely seem relieved and perhaps the fatigue is even greater in the hypothyroid state. "I am no longer conscious of my heart's beating," or words to that effect is often said by patients after the operation.

V The Operation and Complications

The operative technique of total thyroidectomy has been described fully elsewhere. It should be emphasized that this procedure is a distinctly major one, requiring special training and skill, and a precise knowledge of the anatomy of the field. To be successful all thyroid tissue must be ablated and injury of the recurrent laryngeal nerves and accidental removal of parathyroid tissue must be carefully guarded against.

In our series the duration of the operation has varied from one hour up to two hours and forty minutes, with an average time of two hours and ten minutes for completion.

Anesthesia. In the first case of the series regional ether anesthesia was used successfully. All subsequent operations were started under local anesthesia (cervical nerve block and local infiltration). In one case supplementary ether and in another supplementary gas was required because of marked restlessness. Considerable judgment and care have proved to be necessary in the selection of the type and amount of preoperative medication, and this must be varied with every case. These patients do not withstand large amounts of sedation and it has been pointed out that it is not wise to have them too drowsy. We have found it advisable to test out the patients for drug idiosyncrasy several days before operation. The average amount of sedation used has been three grains of amylal or a similar drug at bed time, the same repeated two hours before operation with morphine one sixth grain on call to the operating room. Cases No 8 and No 12 may be cited as examples of oversedation. In case No 8 scopolamine was used without previous test dosage and the excitement caused by it necessitated further morphine and ether, probably contributing to the fatal outcome.

Operative Deaths. There have been three op-

erative deaths in this series. Two of these cases No 8 and No 12 may have resulted from oversedation and in case No 8 quite likely from the added factor of supplementary ether. The third death, case No 9, arose from the operation having been done on a patient who was too seriously sick to withstand the procedure and who should not, we now realize, have been selected for this form of treatment. (See below.)

Nerve Injury. We have been fortunate in having only one nerve injury, the right recurrent laryngeal being cut in the second patient of the series. It might be added that this was the first total thyroid ablation by the surgeon involved.

Hypoparathyroidism. There have been no cases of frank tetany following operation. There have been three persistent cases of hypoparathyroidism (No 3, No 5 and No 19) and two transient cases (No 1 and No 13). None have shown more than subjective symptoms and positive Chvostek signs, and all have been readily controlled by calcium given orally.

TABLE 2

21 Operations	
Average Duration	2 hours 10 minutes
Operative Deaths	3
Nerve Injury	1
Hypoparathyroidism	5 cases

Persistent	3

VI Postoperative Management and Complications

The majority of the patients have left the hospital from two to three weeks after the operation. At the time of discharge the metabolism has usually shown a drop of ten to fifteen points. Instructions are given to lead a quiet chair and bed life for the following two weeks after which time a reexamination is made at the clinic and gradually increasing activity is permitted if the metabolism has shown a satisfactory drop. The rapidity of fall in the basal metabolism has been extremely variable. Usually one month after operation the rate has been in the minus twenties, but without the patients showing signs of definite myxedema.

It may be said that there seems to be considerable discrepancy between the patient's appearance and his basal metabolism test. Roughly a level of between minus twenty and minus thirty has seemed to be the optimum range for maintenance but some have shown definite myxedema signs at minus twenty, while others have maintained a level of minus thirty without marked signs.

In some cases signs and symptoms of myxedema requiring thyroid for the patient's com-

foit have appeared within two months, and in other cases have not appeared for five to eight months Metabolic rate readings have ranged from minus eighteen to minus thirty-seven at the time thyroid was started All of the patients surviving a period of six months have required some thyioid, excepting case No 3 which has shown thyroid regeneration and case No 6 where over the survival period of two years a rate of minus thirty was maintained without untoward myxedema symptoms In all instances thyroid has been started on the basis of symptoms such as marked swelling of the eyes with lacerimation, extreme coldness, or undue somnolence, rather than on the basis of the metabolic rate It has been the aim to keep the metabolism as low as compatible with comfort

Very small dosage of thyroid has often sufficed A quarter grain dose of thyroid every other day has frequently been sufficient to bring about a distinct change in the appearance and feeling of these people In some cases one quarter grain daily has been required, but rarely more

Digitalis dosage at first has been maintained as before operation, but in a number of the cases tolerance appears to have been decreased with the lowering of the metabolic rate and it has been necessary to cut the regular allowance in half Several mild cases of digitalis intoxication appeared

Menorrhagia, thought to be associated with the hypothyroidism, has appeared in two patients of the series, and has required x-ray therapy

The majority of the males have been impotent following the operation

In one case, a patient with hypertrophic arthritis and poor peripheral circulation, joint pains were more severe following operation and attacks of intermittent claudication occurred

In several cases abdominal distention was a troublesome feature, but increase in thyroid usually brought relief from this

Auricular fibrillation was present in fifteen cases before operation, but in only two did it cease following operation In one of these, paroxysms of fibrillation have occurred since and have been quite troublesome

Mental slowing has been present to a certain extent in about half of the cases

Regular follow-up at one to three month intervals has been necessary In some cases the patients have leveled off well on fixed rations of thyroid and digitalis after the first few months In others frequent readjustment of dosage has been found necessary and it has been with some difficulty that the middle course between that of severe cardiac symptoms and

troublesome myxedema symptoms has been followed (See case No 15)

VII Results

The evaluation of results in a given case is most difficult The inherent uncertainty of prognosis in the cardiac patient must always be kept in mind Against the benefits in certain cardiac symptoms must be balanced the undesirable effects of myxedema Again a patient may show decrease in one cardiac symptom, but if consigned to an increased life of uncomfortable invalidism the operation is hardly to be considered worth while

We have classified the patients in two ways First we have grouped them under one of the following classifications

- A No recurrence of signs or symptoms Activity increased Excellent result.
- B Symptoms less severe with increased activity Moderately improved
- C Symptoms less severe without increased activity Slightly improved
- D No improvement Poor result

Secondly, we have tried to determine whether all factors considered, the operation was worth while

Table 3 presents a comprehensive survey of the patients studied with the classification made under "Results" and "Operation Worth While" A Summary of these results in the total group is presented in table 4

TABLE 4			
Summary of Results		Total Group of 21 Cases	
A	1 case	Worth While	
B	3 cases		
C	5 cases	Yes	5 23 8%
D	12 cases	No	16 76 2%
(1 case of thyroid regeneration)			

There are eight cases which in retrospect and which in view of our present knowledge we would not consider suitable for operation for the reasons given below

- Case No 2 Heart disease too severe Patient developed ascites and hydrothorax on bed rest and digitalis Done as a last resort
- Case No 6 Heart disease too severe Patient had a persistent ascites in spite of bed rest and digitalis
- Case No 7 Heart disease too rapidly progressive Syphilitic heart disease
- Case No 9 Severe hypertension and generalized arteriosclerosis Patient was too sick for operation
- Case No 11 Heart disease too severe with marked hypertension

LEGENDS

RHD—Rheumatic Heart Disease
HHD—Hypertensive
SHD—Syphilitic
OP—Operative Death
SLT—Slight
Perm.—Permanent

- Case No 17 Heart disease too rapidly progressive
- Case No 18 Heart disease too severe and too rapidly progressive
- Case No 21 Heart disease too rapidly progressive Previous pulmonary infarction

Assuming that in any future operations we would not select patients of the above type, it seems worth while to see what their elimination from the present series does to our figures This calculation is presented in table 5,

TABLE 5

SUMMARY OF RESULTS IN 13 WELL SELECTED CASES

Group	Cases	Worth While
Group A	1 case	
Group B	3 cases	
Group C	3 cases	Yes 5 38 5%
Group D	6 cases	No 8 61 5%

Assuming that with a larger series and greater experience, perfection in operative technique and handling might be attained, it may be fair to examine the results eliminating from the above the one case of failure of total thyroid ablation (No 3), and the two cases of operative death which probably arose from unwise sedation (No 8 and No 12)

TABLE 6

SUMMARY OF RESULTS IN 10 WELL SELECTED AND WELL MANAGED CASES

Group	Cases	Worth While
Group A	1 case	
Group B	3 cases	
Group C	3 cases	Yes 5 50%
Group D	3 cases	No 5 50%

The present series is not of sufficient size to make significant comparison of results in special types of heart disease or in specific valve lesions Regarding angina pectoris, we have only two patients, one doing well and one doing poorly In the two cases of straight hypertensive heart disease with failure, one was poorly selected and did poorly, the other was classed as a C result but seemed to be worth while Of the four rheumatics complicated by hypertension, two were poorly chosen, one was a B result and definitely worth while, and one was a D result and not worth while Of the twelve straight rheumatics, four were poorly chosen, one was an A result one was a B result, two were C results and four were D results, two of this group were considered worth while

VIII Case Summaries

For the sake of brevity in a rather lengthy report, details of past history, family history, and laboratory findings are not included in the following summaries where not germane to the

subject in question In all cases N P N's and renal function were determined to be normal preoperatively In no case was evidence of active infection such as elevated white count or sedimentation rate present All cases were checked with chest plates and failed to show any pulmonary disease or unusual mediastinal shadows There were no cases with any concomitant chronic disease not mentioned In no case did the pathological examination show evidence of thyroid hyperplasia When thyroid dosage is mentioned, U S P Thyroid (Aimour's) is understood in each case

CASE 1 H C No 329747 F Aged thirty five Native Housewife

Diagnoses Rheumatic heart disease, mitral stenosis and regurgitation, aortic regurgitation, auricular fibrillation, hypertension, congestive failure

History The patient entered the medical service June 7, 1933 Eleven years previously she was told that she had a heart murmur, but up to that time there had been no history of rheumatic infection or heart trouble Six years before she had been in bed for four months with migratory joint pains, fever, and "water about the heart" Since that time there had been marked fatigue, dyspnea on exertion, orthopnea requiring four to five pillows, palpitation, localized precordial pains, and a constant cough During the four winters previous to entry, she had suffered breaks in compensation with painful liver, nausea and gross edema, each attack becoming progressively more severe During the winter prior to entry she was in bed for four months and for the following three months, up to the time of entry, was restricted to a bed and chair life without any activity She was having cardiac asthma two to three nights a week She had received careful medical care with full digitalization and maintenance

Physical Examination The patient showed moderate cyanosis The heart was distinctly enlarged to the left, grossly irregular in action, and showed apical systolic and middiastolic murmurs, also a basal diastolic murmur to the left of the sternum The blood pressure was 170/90 The lungs were clear The liver was enlarged and tender The ankles showed slight edema.

B M R level was zero

Rationale for Operation This patient had been suffering from mild, progressive heart failure for six years and had been totally incapacitated for seven months on medical treatment without prospect for improvement It was hoped that operation might bring increased comfort and activity

Operation July 13, 1933 Anesthesia Ether Complications Positive Chvostek and Trousseau were present for two weeks, but controlled by calcium given orally, operative recovery was otherwise normal

Postoperative Course For practically two years following operation the patient was very much improved There were no gross breaks in compensation There was but little dyspnea on exertion, patient slept on one or two pillows, there was no edema, no cardiac asthma, and almost no precordial pain Palpitation was noted only on going upstairs She was able to help with the housework and get the night meal for the family Her B M R after the first month ranged about minus twenty After the sixth month thyroid was given in amounts varying from one quarter to one eighth grain daily, because of increasing fatigue, coldness and lacrimation

tion. The patient was able to concentrate less well than previously found difficulty in mathematical calculations and to a slight extent with her memory. During February, March and April 1935 she had severe hemorrhage requiring hospitalization. No evidence of pelvic tumor could be found and x-ray treatment was given with cessation of flow. About the first of July she reentered the hospital with an unexplained fever, a palpable spleen and liver and a few petechial spots. Blood cultures were negative. July 17 she died with the questionable diagnosis of subacute bacterial endocarditis. No autopsy was obtained.

Result This patient represents a very good result with a definitely improved cardiac state up to the time of her death from acute infection two years after operation. From her mild myxedema she had some slight mental impairment and the probable complication of hemorrhage, in spite of which the operation was very much worth while to her.

Comment This proves to have been a well selected case. While the patient had severe heart disease it was slowly progressive over a period of a number of years, and signs of failure were well controlled by digitals and diuretics.

CASE 2 D P No 306061 F Aged forty-eight Italian Housewife.

Diagnosis Rheumatic heart disease, mitral stenosis and regurgitation, aortic stenosis and regurgitation, atricular fibrillation, congestive failure.

History This patient entered the hospital June 9, 1933 for the second time with congestive heart failure. There was no past history of chorea or rheumatism. For twenty-one years she had noted weakness, dyspnea and mild edema of the ankles off and on. For four years palpitation, cough, epigastric pain and precordial distress had been troublesome. Six months previously she was admitted to the hospital for gross congestive failure with abdominal and chest fluid which was relieved by digitals and salyrgan. Following discharge in spite of maintained digitalization and bed rest, she was required to lead a chair and bed existence and again developed gross signs of failure.

Physical Examination There was marked orthopnea and cyanosis. The heart was grossly enlarged to the left, fibrillating and showed mitral and aortic systolic and diastolic murmurs. The blood pressure was 100/80. There was a right hydrothorax extending to the angle of the scapula. The liver was felt six cm. below the costal margin. The abdomen showed a fluid wave and shifting dullness. The sacrum and legs were edematous.

B M R level was plus one

Rationale for Operation This patient's optimal state appeared to be one of congestive failure and the outlook for improvement appeared hopeless. It was felt that it would be fair to offer her the possible advantage of total thyroidectomy. On salyrgan the patient lost fifteen pounds of edema fluid and operation was determined on.

Operation August 8 1933 Anesthesia Local. Complications The right recurrent laryngeal nerve was cut resulting in paralysis of the right cord. There were no signs of tetany.

Postoperative Course The patient was discharged August 23 1933. During September and October she seemed slightly improved, having less dyspnea and palpitation and very little edema. However she continued to lead a chair and bed life. November 1

1933 the B M R. was minus twenty-six. December 14 the patient reentered the hospital because of increasing ascites, edema and orthopnea of six weeks duration. The following morning she died.

Result For two months after operation there appeared to be very slight improvement, but it would be difficult to say that this resulted from operation rather than from the prolonged absolute bed rest and diuretics under observation. In spite of the operation gross failure shortly set in again and proved fatal.

Comment This was one of the first cases to be done and at that time we did not appreciate the fact as we do now that cases having such low cardiac reserve as to develop ascites or hydrothorax on rest and digitals are too hopeless to be benefited by operation. This patient should never have been operated on.

CASE 3. H P No 330660 F Aged thirty Italian Housewife

Diagnosis Rheumatic heart disease, mitral stenosis and regurgitation, atricular fibrillation, congestive failure.

History This patient entered the hospital July 20 1933. Six years before she had been in bed three months with rheumatic fever and was then told that she had a bad heart. Four years before there was a recurrence of rheumatism followed by onset of progressive dyspnea and palpitation. Eight months before entry edema of legs set in and became massive. For two months the patient was confined to her bed. For one week there had been orthopnea requiring the patient to sit up straight. She had been on digitals for several months.

Physical Examination There was marked cyanosis. Neck veins were distended with the patient sitting up straight. The heart was grossly enlarged showing apical systolic and mid-diastolic murmurs. rhythm was grossly irregular with an apical rate of one hundred and sixty and a pulse of ninety. There were moist rales at both lung bases and the liver was felt six cm. below the costal margin and distinctly tender. There was a small amount of abdominal fluid. The legs and sacrum showed gross pitting edema. Salyrgan and Southeby tubes were required for the elimination of excess fluid.

B M R Unfortunately only one rate was obtained and this on the morning of operation after sedation the previous night. It was minus sixteen. (Subsequent events suggest true rate was higher.)

Rationale for Operation It was considered that with conditions as they were the prognosis in this case was very poor and little could be offered other than the possible benefit from total thyroidectomy.

Operation August 15 1933 Anesthesia Local. Complications Positive Chvostek and Trousseau appeared the day following operation and calcium by mouth has been required since. There was no frank tetany.

Postoperative Course Three weeks after operation the B M R. was minus twenty-one. Pulse had become regular. The patient was up and about the ward with very much less dyspnea and palpitation and there was no edema. For about five months there seemed to be some improvement with less dyspnea, palpitation and orthopnea. Then there was a gradual recurrence of edema and swelling of the abdomen. July 1 1934 she reentered the hospital in gross congestive failure with pitting edema and ascites requiring paracentesis. Her B M R. at that time was minus twenty-nine although there were no signs or symptoms of myxedema. Following this

- Case No 17 Heart disease too rapidly progressive
- Case No 18 Heart disease too severe and too rapidly progressive
- Case No 21 Heart disease too rapidly progressive Previous pulmonary infarction

Assuming that in any future operations we would not select patients of the above type, it seems worth while to see what their elimination from the present series does to our figures This calculation is presented in table 5,

B M R level was zero

Rationale for Operation This r fering from mld, progressive years and had been totally In months on medical treatment improvement It was hoped bring increased comfort an

Operation July 13, 1933 pllcations Posltve Chvc present for two weeks, given orally, operative r mal

Postoperative Course following operation th proved There were tion There was bu tinent slept on one edema, no cardlac pain Palptatior stals She was and get the night mea after the first month ran After the sixth month thyrolda varying from one quarter to one e because of increasing fatigue, coldness

before operation. Possibly her life was prolonged. From the scientific point of view the operation produced definite cardiac benefit. Viewing the situation as a whole we do not consider the procedure to have been worth while for this patient.

CASE 5 F G No. 251759 M. Aged fifty-two Irish. Unemployed.

Diagnoses Hypertensive and coronary heart disease, angina pectoris auricular fibrillation congestive heart failure

History This patient entered the hospital September 6 1933 for the seventh time because of heart trouble. He had been partially disabled for ten years and almost totally so for five years with dyspnea, palpitation orthopnea and intermittent edema. For three years he had suffered attacks of crushing precordial pain radiating down the left arm coming with any exertion, and relieved by nitroglycerine.

Physical Examination There was moderate cyanosis and respiratory distress. The heart was grossly enlarged sounds of poor quality and a basal systolic murmur was present rhythm was totally irregular. The blood pressure was 150/130. There was marked arteriosclerosis. There were rales at the lung bases. The sacrum and legs showed a moderate edema.

B M R. level was plus twenty-five

Rationale for Operation Since this patient suffered from congestive failure which he was able to clear on bed rest, as well as from angina pectoris which was incapacitating it was felt that total thyroidectomy should offer some benefit especially to view of the elevated metabolism. The operation was done primarily for angina.

Operation September 27 1933 Anesthesia Local Complications None.

Postoperative Course Following the operation this patient rested in the hospital for a month and was then discharged to a convalescent home. There leading a quiet life, the number of attacks increased although no signs of congestive failure appeared. He died suddenly on December 11 1933 two and a half months after operation of pulmonary thrombosis and infarction, as revealed by autopsy. There was also found to be marked coronary atherosclerosis and localized areas of fibrosis of the myocardium.

Result In this patient's relatively short postoperative course, we see no improvement in the angina, but on the contrary his anginal attacks became more frequent in number. There was no return of congestive failure in the two and one-half months postoperative course.

Comment The presence of pulmonary thrombosis probably in part explains the unsatisfactory course with this patient.

CASE 6 S R. No. 237519 F Aged forty-three Irish. Housewife.

Diagnoses Rheumatic heart disease, mitral stenosis and regurgitation ? tricuspid stenosis auricular fibrillation congestive failure, ? portal obstruction.

History October 16 1933 this patient was admitted to the hospital for the twelfth time in six years with congestive heart failure. From the ages of twelve to twenty-five she had frequent attacks of joint pain. For six years prior to this entry there had been dyspnea, palpitation and edema. For three years there had been orthopnea requiring three or four pillows at night cardiac asthma occurred almost weekly and activity was limited to walking from one room to another. During this time ascites set in, requiring abdominal taps about every eight

days with removal of six to eight quarts of fluid.

Physical Examination There was moderate cyanosis. Neck veins were distended. The heart was grossly enlarged fibrillating and showed apical systolic and diastolic murmurs. The blood pressure was 160/90. There was fluid in the left chest and rales at the lung bases. The abdomen was distended with fluid. The liver was palpable twelve cm. below the costal margin. The legs showed a marked pitting edema.

B M R level was minus five

Rationale for Operation Regarding diagnosis the question was raised whether this case represented simply rheumatic heart disease with a possible cardiac cirrhosis or some other type of portal obstruction giving rise to the marked ascites. It was felt that on theoretical grounds, with the lessened necessary blood flow going with a lowered metabolic rate the ascites might be relieved. Furthermore it was believed that increased circulatory failure might be prevented. Without previous experience in this type of case it was decided with consent of the patient, to proceed with total thyroidectomy on a purely theoretical and experimental basis.

Operation November 7 1933 Anesthesia Local Complications None.

Postoperative Course For the first nine months postoperatively the interval between abdominal taps was cut down to about once in two weeks but following that, they were again required almost weekly. Other signs and symptoms were little if any improved although asthma did not occur for the first nine months and was of rare occurrence thereafter. Several chest taps in addition to the abdominal taps were required. The B M R remained about minus thirty but the patient showed no untoward myxedema symptoms. October 25 1935 two days after her final tap the patient grew increasingly weak and died, the exact cause of death being uncertain. No autopsy was obtained.

Result The operation in this case brought about no worth while benefit.

Comment This case illustrates the futility of the procedure in cases of long standing, intractable, severe congestive failure, and in cases with persistent ascites. This patient should not have been operated on.

CASE 7 J D B M No. 11473 M Aged fifty Native. Coal Dealer

Diagnoses Syphilitic aortitis aortic regurgitation congestive failure.

History This patient entered the hospital October 9 1933. For six months he had presented rapidly progressive signs and symptoms of congestive failure with dyspnea and cough. For two months he had remained in bed with increasing edema in spite of digitalis. At the age of twenty he had had a chancre.

Physical Examination There was moderate cyanosis and engorgement of the neck veins. The heart was grossly enlarged showing a very loud aortic diastolic murmur. Blood pressure was 170/50. There were a few rales at the lung bases. The liver was felt six cm. below the costal margin. There was a moderate amount of abdominal fluid. The sacrum and extremities showed marked edema.

B M R not done. Hinton Strongly positive.

Rationale for Operation Because of failure to improve after a month of hospitalization it was felt that thyroidectomy as a last resort was justifiable with a hope of decreasing the congestive failure in spite of the ultimate poor prognosis.

Operation November 8, 1934 *Anesthesia* Local
Complications None

Postoperative Course There was not any apparent benefit or effect from the operation November 24, 1934, sixteen days later the patient died at home
Result No benefit from operation

Comment This again was one of the early cases operated on as a last resort and we have learned that this does not pay We have also come to feel that the operation is not worth while in cases of syphilitic heart disease because of the rapidly progressive nature of the lesion

CASE 8 H K No 332819 M Aged forty two
Hebrew Junk collector

Diagnoses Rheumatic heart disease, mitral stenosis and regurgitation, auricular fibrillation

History This patient entered the hospital October 20, 1933 For eight years there had been increasing dyspnea on exertion For four years there had been marked dyspnea, palpitation, orthopnea, and the patient had been unable to work For two years there had been increasing edema For three months the patient had led a chair and bed life Digitalization had been maintained in the Out-Patient Department for eight years

Physical Examination There was moderate orthopnea, marked cyanosis and the neck veins were distended The heart was grossly enlarged to the left, fibrillating and showed apical systolic and diastolic murmurs The blood pressure was 124/80 There were moist râles at the lung bases The liver was palpable at the umbilicus and tender There was pitting edema of the sacrum and legs

B M R level was plus five

On bed rest and diuretics the edema disappeared

Rationale for Operation In view of the chronically crippled condition of the patient, in spite of adequate medical care, it was felt that thyroidectomy offered the only chance for improvement

Operation November 8, 1933 *Anesthesia* Morphine one sixth grain s.c. at 7 00 A.M. Morphine one sixth grain, atropine one one-hundredth grain and scopolamine one one hundred and fiftieth grain s.c. at 8 25 A.M. Operation started with novocaine one per cent infiltration at 9 25 A.M. Because of restlessness and excitement, morphine one sixth grain was given at 10 25 A.M. and the remainder of the operation completed under drop ether

Postoperative Course The patient did well for twelve hours and at that time the blood pressure dropped, temperature rose, lungs became filled with moisture and the patient died

Result Operative death

Comment Since the time of operating on this patient we have learned that these cardiacs sustain large amounts of sedation poorly We have also learned that it is wise to test out reaction to proposed medication in advance of the day of operation Excitement, possibly from scopolamine, necessitating additional morphine and ether, quite likely led to the termination in this case

CASE 9 H K B M No 11774 Aged fifty four
Native Architect

Diagnoses Hypertensive heart disease, generalized arteriosclerosis, auricular fibrillation

History This patient was admitted to the hospital November 4, 1933 For five months he had a noted fluttering and pounding of his heart, and for three months there had been dyspnea on any exertion and slight swelling of the feet at night For ten years there had been a known hypertension Recently he had been very nervous and was rapidly losing ground

Physical Examination The heart was markedly enlarged with sounds of poor quality, harsh systolic murmur in the aortic area and fairly loud blowing apical systolic murmur Blood pressure 220/140 Lungs showed occasional râles at bases Legs showed a slight pitting edema

B M R was plus twenty seven (Patient very nervous and true rate hard to obtain)

Rationale for Operation This patient was unable to work, nervous, discouraged and having some evidence of disorientation The operation was done with the hope of delaying his cardiac failure

Operation November 9, 1933 *Anesthesia* Local
Complications There was Cheyne-Stokes respiration during the operation The patient did not recover from a state of stupor and died a few hours later

Result Operative death

Autopsy showed very advanced arteriosclerosis with beading of the cerebral vessels in addition to hypertensive heart disease

Comment The high degree of hypertension and the marked generalized and cerebral arteriosclerosis would in view of later knowledge be considered contraindications to operation

CASE 10 S C No 319289 M Aged sixty
Russian Hebrew Unemployed.

Diagnoses Hypertensive heart disease, congestive failure, auricular fibrillation

History This patient entered the hospital for the second time, November 2, 1933 Twenty five years before he was seen in the Out Patient Department complaining of palpitation, and at that time showed cardiac enlargement with a total irregularity and pulse deficit Since then he had been followed, because of increasing dyspnea and palpitation Fifteen months prior to the present entry he was sent to the medical wards because of increasing heart failure with orthopnea, pulmonary congestion, engorged liver and slight edema On bed rest, continued digitalis and diuretics he improved After leaving the house his course was again one of increasing disability, with persistent moderate signs of congestion Intermittent, localized sharp precordial pains appeared For six months he had been confined to a chair and bed life, because of severe dyspnea and orthopnea requiring four pillows and palpitation

Physical Examination The heart was moderately enlarged, no murmurs were heard, the pulmonary second sound was accentuated, and rhythm was grossly irregular Blood pressure was 210/110 The lungs showed moist râles at the bases The liver was felt four cm below the costal margin. There was no edema

B M R level was plus three

Rationale for Operation This patient was totally incapacitated on full digitalization and showed signs of progressive cardiac failure It was believed that he could be given greater activity with retardation of terminal failure by the operation

Operation November 10, 1933 *Anesthesia* Local
Complications None Uneventful recovery

Postoperative Course For about fourteen months following operation this patient seemed slightly improved. His activity was increased to the point of walking one quarter to one half mile in a day. Orthopnea disappeared and he slept well on two pillows. There was no palpitation. Dyspnea became distinctly less. There was practically no edema. Pre-cordial aches were almost entirely relieved. On the other hand he felt generally weak and became tired very easily. It was fatigue rather than dyspnea which limited his activity. Because of marked puffiness about the eyes lachrimation cold and increasing fatigue one quarter grain of thyrold daily was started during the second postoperative month and was continued thereafter with the B. M. R. ranging between minus fifteen and minus twenty. Digitalis one and one-half and three grains were continued on alternate days.

During the winter of 1934 and 1935 the patient minded the cold far more than previously. Old hypertrophic arthritis gave increasing pain. Peripheral circulation became very poor and attacks of intermittent claudication set in. During the spring the patient grew generally somewhat weaker more dyspneic and was forced to lead a very quiet life. In June 1935 he had a cerebral hemorrhage from which he never recovered dying on June 28, 1935.

Result This patient's cardiac status was definitely improved by operation and impending gross failure was warded off but the side effects of the myx edema were distinctly troublesome and he was ill in all a rather miserable patient.

CASE 11. G. K. B. M. No. 11859 F. Aged forty seven. Native Housewife

Diagnosis Rheumatic and hypertensive heart disease, mitral stenosis auricular fibrillation congestive failure.

History This patient entered the hospital November 12, 1933. For five years there has been marked dyspnea and palpitation on exertion and for four years she was able to do little housework because of this. For two years there had also been swelling of the ankles at night and orthopnea. During the previous year there had been five severe attacks of paroxysmal dyspnea palpitation cough and frothy sputum each requiring three to four weeks in bed. The patient had been resistant to digitalis and had required four and one-half grains a day constantly to control the apex rate.

Physical Examination There was moderate respiratory distress and cyanosis. The heart was grossly enlarged totally irregular and showed an apical diastolic murmur. Blood pressure was 250/170. There were moist rales at the lung bases. The liver was palpable six cm below the costal margin. There was moderate edema of the legs.

B. M. R. level was plus seventeen.

Rationale for Operation This patient was laid up frequently with tachycardia (auricular fibrillation and orthopnea) and was losing ground steadily in spite of adequate medical care.

Operation November 18 1933. Anesthesia Local. Complications None.

Postoperative Course The immediate effect of operation was one of striking benefit. The heart became slow palpitation disappeared and the patient was able to lie flat without discomfort. There was a great deal of psychic trauma from the operation under a local anesthetic and she was troubled with bad dreams for months afterward on returning home. Dyspnea on exertion some edema headache and abdominal distention continued to incapacitate her for any activity other than walking about her room.

Attacks of paroxysmal dyspnea recurred. She again required three to four pillows at night. She was taking three grains of digitalis a day and one half grain of thyrold every other day was required for myxedema symptoms after the second month.

In March, 1935 (eleven months after operation) the patient's local doctor felt that she was too myxedematous and not doing well, so raised her thyrold to one grain daily (no B. M. R. was taken) and at the same time increased her digitalis to four and one-half grains daily. Following this some of the puffiness of her face and ankles decreased. Gradually signs and symptoms of failure increased with earldoe oedema occurring almost nightly. Nausea set in and all digitalis was omitted for a week. May 7 1935 the patient reentered the hospital in congestive failure. At this time her B. M. R. was plus seven. During an eighteen day rest in the hospital off thyrold her rate fell to a level of about minus fifteen. Digitalization was reestablished on one and one-half and three grains daily. Symptoms were somewhat improved.

After returning home the patient was again confined largely to a chair and bed life with moderate congestive failure. July 20 1935 twenty months after operation she suddenly developed acute pulmonary edema and died within a few hours.

Result There was little if any benefit from the operation in this case and it was certainly not worth while.

Comment This again is a case of very severe heart disease with marked hypertension which should not be selected for operation today.

CASE 12. L. H. No. 263901 M. Aged thirty three. Hebrew Unemployed.

Diagnosis Rheumatic heart disease mitral stenosis and regurgitation aortic regurgitation auricular fibrillation congestive failure.

History This patient was admitted to the medical service January 24 1934. At the age of thirteen he was in bed for eight months with rheumatic fever. For ten years there had been some increasing dyspnea on exertion. For five years palpitation had become increasingly troublesome. In the previous three years there had been three attacks of congestive failure with cough, orthopnea and liver pain, the last setting in three weeks before entry. Between attacks he had been able to walk only a few blocks without exhaustion.

Physical Examination There was moderate cyanosis and neck veins were pulsating. The heart was grossly enlarged to the left, fibrillating and showed mitral systolic and diastolic murmurs also an aortic diastolic. The blood pressure was 145/90. There were rales at both lung bases. The liver was palpable and tender eight cm. below the costal margin.

B. M. R. level was plus eleven.

Rationale for Operation In view of repeated breaks in compensation without massive edema responding well to bed rest and digitalis but with an obviously low reserve, it was believed that operation should be of marked benefit in this case.

Operation February 16 1934. Anesthesia Lu. Minimal three grains at bed time pentobarbital three grains at 7:00 A.M. pantopon one third grain s.c. at 7:30 A.M., pantopon one third grain s.c. at 8:00 A.M., pantopon one third grain s.c. at 8:30 A.M. operation started at 8:50 A.M. Novocaine one per cent cervical block and infiltration. The thyrold was easily removed in toto. No parathyroids removed. No nerve injury. The patient's condition remained good during the operation.

Postoperative Course The patient's condition re-

mained fairly good up to 4 10 P M when he suddenly became cyanotic with irregular, gasping respiration, pulse of one hundred and blood pressure 140/80. He became unconscious, in spite of oxygen therapy, respirations grew weaker and more irregular, blood pressure dropped to 80/40. At 3 35 A.M. the following morning, some sixteen hours following operation he died in apparent respiratory failure.

Result Operative death. No autopsy.

Comment It is possible that a cerebral embolus to the respiratory center may have been the cause of death in this case. Again, as in case 8, we note that a large amount of sedation was given which we have since learned these people tolerate poorly.

CASE 13 E J P P H No 32923 F Aged thirty-nine Native Housewife

Diagnoses Rheumatic heart disease, mitral stenosis, auricular fibrillation

History This patient entered the hospital February 12, 1934. Fifteen years before she developed a cough which had continued since, and shortly thereafter dyspnea on exertion set in and grew progressively more marked. During the previous six years palpitation had been severe and constant. For one year there had been frequent localized heartache. Hemoptysis had occurred on four occasions in the previous six years. For three years there had been fullness in the abdomen and on one occasion definite congestive failure requiring ten weeks' rest in bed. Digitalization had been maintained for several years.

Physical Examination The heart showed marked enlargement to the right. There was a long, loud apical mid diastolic murmur. The rhythm was totally irregular. The lungs were clear. The abdomen was distended with the liver palpable five cm below the costal margin and slightly tender. There was very slight pitting edema of the lower shins.

B M R level was minus nine.

Rationale for Operation Because of marked discomfort and slowly progressive cardiac invalidism in spite of careful medical attention it was felt that total thyroidectomy should be tried.

Operation February 20, 1934. Anesthesia. Local Complications. The patient developed a positive Chvostek of a few days' duration only. No cord injury or frank tetany.

Postoperative Course Two months after operation dyspnea, cough, precordial ache and palpitation had distinctly improved. The *B M R* was minus six, the face and eyes had become markedly puffy, and thyroid one half and one quarter of a grain on alternate days was given. For fifteen months after operation the favorable progress continued, she was able to manage her house, walk one-quarter to one-half mile a day, be more active and feel better than in years. *A B M R* in May, 1935 was minus sixteen. From June to September, 1935 the patient was moderately active with housework, but unable to walk outside because of increasing dyspnea and epigastric fullness. In October, 1935 she again entered a state of gross congestive failure with frothy sputum and edema of the legs. At present she is showing improvement on bed rest and diuretics.

Result This patient has been distinctly improved and benefited by the operation. She and her family considered the result miraculous.

CASE 14 S M No 335331 M Aged thirty-four Native Unemployed (Former shoe worker)

Diagnoses Rheumatic heart disease, mitral stenosis and regurgitation, aortic stenosis and regurgitation, auricular fibrillation, congestive failure.

History This patient entered the medical service March 14, 1934. At the age of seven he had had chorea and at twelve, severe tonsillitis, there was no history of rheumatism. He was well up to five years before entry when he gradually developed dyspnea on exertion which had continued and become progressive. Three years before he developed a sense of fullness in the abdomen and marked palpitation. He entered a local hospital where he remained for two weeks being digitalized and receiving diuretics. The fullness in the abdomen subsided, but the palpitation continued. For two and a half years prior to entry he had been unable to work because of severe dyspnea and palpitation on walking even one block on the level. During this time he had cardiac asthma on four occasions. He slept on two pillows. He never had edema of the extremities. He was able to be up and about the house. He was taking digitalis one and a half and three grains on alternate days.

Physical Examination The heart showed marked generalized enlargement, with apical systolic and diastolic murmurs, also basal systolic and diastolic murmurs with a systolic thrill, rhythm was grossly irregular with a rate of seventy. Blood pressure was 115/50. The lungs were clear. The liver edge was just palpable but nontender. There was no edema.

B M R level was plus six.

Rationale for Operation This patient had been quite incapacitated for any activity for two and a half years because of dyspnea and palpitation without gross edema. It was believed that operation would increase his general comfort and activity, and might permit a return to work.

Operation April 4, 1934. Anesthesia. Local Complications. None. Uneventful operative recovery.

Postoperative Course Since operation, now eighteen months ago, this patient has done very well. Within six weeks he was able to walk a half mile without any palpitation and almost no dyspnea. He now walks two miles a day, has no palpitation, and has only slight dyspnea going up hill or over stairs. He takes care of the furnace and helps with housework. He is looking for a job, but has yet not found one. He sleeps well on one pillow. He has had no cardiac asthma. There are no signs of congestive failure. Two months after operation with a *B M R* of minus twenty-one he was started on one quarter grain of thyroid every other day because of lethargy and sleepiness. He has continued on this dosage maintaining a rate about minus twenty-five without untoward myxedema symptoms. He is taking one pill of digitalis daily. His only present complaint is easy fatigability.

Result This patient represents a very good result. His presenting symptoms have been almost entirely dissipated. He should be able to work when he finds a job which does not demand too strenuous activity.

CASE 15 S D No 336686 F Aged forty-two. Russian Hebrew Housewife

Diagnoses Rheumatic heart disease, mitral stenosis and regurgitation, aortic stenosis and regurgitation, auricular fibrillation, congestive failure.

History This patient entered the hospital for the first time April 23, 1934. Thirty years previously, at the age of twelve, she had rheumatic fever and was in bed for three months. Twelve years before she noted onset of palpitation and dyspnea which had continued and progressed since. Six years be-

fore she was forced to give up work in a restaurant because of severe dyspnea. Nine months prior to entry cardiac asthma first occurred and had been present almost nightly since. During this period the patient required three to four pillows for rest and palpitation and dyspnea were so marked that activity was limited to a chair and bed life. She had been fully digitalized.

Physical Examination. The patient was sitting upright in bed with difficult breathing. The neck veins were engorged. The heart was enlarged to the left, showed double mitral and aortic murmurs and was totally irregular with an apical rate of ninety. The liver was not enlarged. There was no edema. B M R level was plus eleven.

Rationale for Operation. It was believed that operation alone might offer further relief to this patient. Because symptoms of left sided failure predominated without gross edema, it was felt that she should be a favorable subject and while her activity might not be greatly increased she should be made far more comfortable.

Operation. May 18 1934. Anesthesia Local. Complications None.

Postoperative Course. This patient illustrates well some of the difficulties of postoperative management. For the first two months there was some symptomatic improvement, but no increase in activity. B M R fell to minus nine. The rhythm had returned to normal. During July severe attacks of palpitation occurred associated with choking sensations, presumably paroxysmal fibrillation. Dyspnea became as severe as before operation. B M R rose to minus two and there were no signs or symptoms of myxedema. Catamenia was three weeks overdue and the question of possible pregnancy arose. An Aschheim Zondek test was negative. In early August the B M R dropped to minus twenty-eight and mild signs of myxedema appeared, but the patient's general state was as poor as before operation.

August 31 1934 the patient was readmitted to the house because of paroxysms of palpitation nocturnal dyspnea and several spells of syncope. She had taken one and a half grains of digitalis daily since the operation as before. Electrocardiogram showed sinoatrial block with A V nodal escape beats, digitalis T waves and rate of sixty-five. It was felt that digitalis intoxication was in part responsible for her difficulties and this was omitted for a week and then resumed in one and a half grain doses daily. Because of marked appearances of myxedema (in spite of B M R only minus twenty-two) thyroid one quarter grain daily was started. In September she was still confined to a chair and bed life. A normal catamenia occurred. Because of a pulse of fifty-five to sixty digitalis was omitted every third day. Thyroid was continued. In October conditions were much the same. In early November the patient appeared somewhat improved and was able to be up about the house about half the time. The pulse was down to fifty and the electrocardiogram showed digitalis T waves so digitalis was reduced to one and a half grains every other day. The B M R was only minus ten and the patient did not appear myxedematous so thyroid was omitted. In the middle of November the patient had two severe attacks of palpitation, dyspnea and choking sensations. The B M R was minus twenty-two and the patient's face was quite puffy. Pulse was fifty-six and regular. Quinidine was tried to eliminate the paroxysms of fibrillation but after six grains marked intoxication occurred and the drug was omitted. In mid December the patient reported that there had been no further attacks of palpitation but that dyspnea had grown progressively more severe on the slightest exertion since the

operation had been omitted the month before and that abdominal distention had become more troublesome. The B M R reading was minus seventeen but clinically it appeared to be in the minus thirties. With a pulse of sixty and no signs of congestive failure we felt that the severe dyspnea, weakness and abdominal distention were most likely myxedema rather than cardiac symptoms. A seven foot chest plate at this time showed no change in the size or shape of the heart since operation. (We were wondering if she might show a change to the picture of a myxedema heart.) Thyroid one quarter grain daily was resumed. At the end of December the patient was much improved in every way having much less dyspnea and distention and no other untoward symptoms. B M R was minus seventeen.

From January until about the middle of May 1935 she seemed improved being able to help with the housework, having no palpitation and very little dyspnea on the level. During this period her metabolism was about minus eighteen, on one quarter grain of thyroid daily with a pulse of sixty to seventy on digitalis one and a half grains every other day.

From the end of May 1935 up to the time of writing, October 1935 sixteen months after operation the patient has again failed having some increase in dyspnea with walking on the level, palpitation when active or quiet, orthopnea requiring three to four pillows and has been again forced back to a chair and bed life. In June she had a very profuse period with excessive flowing for nine days. She was readmitted to the hospital for observation. At this time the B M R had risen to minus four (having been only minus twelve in May) and thyroid was omitted. Surgical consultants could find no evidence of pelvic tumor and a course of x-ray over the uterus was given. There has been no menstrual flow since. In August the B M R was minus nine off thyroid but since abdominal distention and general weakness had increased it was felt wise to resume thyroid one quarter grain every other day. In September the B M R was minus thirteen, weakness and distention were decreased, but dyspnea was not improved and several mild attacks of cardiac asthma had occurred.

Result. This patient's course has been one of ups and downs and complications. We do not feel that the operation has been worth while.

CASE 16. W. R. B. M. No. 14214. M. Aged sixty seven. Canadian Physician.

Diagnosis. Angina pectoris, coronary heart disease.

History. This patient entered the hospital June 4 1934. Two years prior to entry he began to notice a pressure pain below the right clavicle appearing on exertion. For the six months before entry he had suffered very severe crushing precordial pain radiating down the left arm coming on walking or any marked exertion and always promptly relieved by nitroglycerine. The various purine drugs were of no value in preventing attacks. There were never any symptoms of congestive failure.

Physical Examination. The heart was at the upper limits of normal size. The sounds were of good quality and there were no murmurs. The lungs were clear. There was no edema. Blood pressure was 118/70.

B M R level was minus seventeen. The electrocardiogram was normal.

Rationale for Operation. The patient was very anxious for the operation and the degree of disability from angina appeared sufficient for its recommendation in spite of the low basal metabolic rate.

Operation June 19, 1934 Anesthesia Local Complications None

Postoperative Course July 20, 1934, one month after operation, the B M R was minus thirty one. August 24, 1934 the rate was minus thirty seven and there was some puffiness of the eyes, thyroid one quarter grain daily was started. In November he started doing some light work and reported that he had had no true angina since operation, but slight soreness over the precordium on exertion. When seen in September 1935, fifteen months after operation, he appeared to be very well, reporting only a little substernal aching on smoking or on walking any distance, but this was promptly relieved by nitroglycerine. His B M R was minus seventeen, but recently he had been taking one grain of thyroid daily, as on this he felt better, although substernal oppression and aching had increased with this dosage. He was advised to reduce this to one half grain daily. He had been able to carry on with his office practice steadily except for a three weeks' vacation.

Result This patient has shown almost complete relief of his anginal symptoms and represents a very satisfactory result.

CASE 17 M S No 335249 F Aged 45 Colored Housewife

Diagnoses Rheumatic and hypertensive heart disease, aortic stenosis, mitral regurgitation, congestive failure

History This patient entered the medical service May 16, 1934 for the second time in congestive failure. There was no past history of rheumatic infection. Fifteen months before she had had a large hemoptysis and then learned for the first time that she had heart trouble. Following that time there was progressive dyspnea and palpitation on exertion, and a constant cough. For six months there had been localized precordial aches and pain over the region of the liver, and during the same period she had slept poorly with three pillows. Three months before February, 1934, she had remained for three weeks on the medical ward with mild congestive failure and was digitalized. Following discharge, in spite of continued bed rest and digitalis, she shortly developed more dyspnea, constant liver pain, nausea, edema of legs and cardiac asthma occurring every other night. She had done no work for fifteen months and had been a chair and bed invalid for six months.

Physical Examination There was a moderate degree of jaundice. The heart showed marked enlargement with apical and basal systolic murmurs and thrills. The pulse was ninety and regular. The blood pressure was 180/124. The lungs showed moist râles at both bases. The liver was enlarged, edge palpable ten cm below the costal margin and definitely tender. There was a small amount of abdominal fluid present. The legs and feet showed pitting edema.

B M R level was plus twelve

Rationale for Operation Because of progressive cardiac failure, producing marked discomfort and total incapacity, in spite of rest and digitalis, it was felt that total thyroidectomy alone might offer relief.

Operation June 10, 1934 Anesthesia Local Complications None

Postoperative Course Following operation for about eight months this patient did well. She was up and about the house all day, got one of the meals, and walked as much as half a mile. She had moderate dyspnea only on going over stairs. She slept well on two pillows. Cardiac asthma ceased except

for two slight attacks associated with respiratory infection. The chronic cough ceased. There was no longer any palpitation, precordial ache, liver pain or edema. Examination showed few râles persisting at the lung bases. Enlargement of liver persisted but the tenderness disappeared. Seven months after operation the B M R fell to minus thirty five, previous levels having been about twenty six. Because of some increasing fatigue, very poor appetite and marked puffiness of the face, thyroid one quarter grain every other day was started. One month later B M R was minus twenty-four and the patient was feeling generally much improved. Nine months following operation cardiac asthma, dyspnea, palpitation and edema returned in increasing degree until ten months after operation the patient was chiefly confined to bed. Digitalis and thyroid was continued as before, B M R's ranging from minus twenty to minus thirty. On August 19, 1935, fourteen months after operation, the patient died in gross congestive failure at another hospital. No autopsy was obtained.

Result For nine months this patient showed some moderate but distinct improvement. She then again grew progressively worse and died in gross failure at the end of fourteen months. We do not consider this result worth while.

Comment The rapid recurrence of the second attack of gross failure, within three months of the first, with the patient remaining practically at bed rest on digitalis, suggests a severity of heart disease and a rapidity of failure which should have been considered a contraindication to operation.

CASE 18 W M No 337153 M Aged thirty six Unemployed

Diagnoses Rheumatic heart disease mitral stenosis and regurgitation, auricular fibrillation, congestive failure

History This patient entered the hospital for the second time in congestive failure July 10, 1934. There was no past history of rheumatic infection. Two years before, following a hernia operation, he first noticed increasing dyspnea, palpitation and cough. One year before he had a hemoptysis. Following that there was orthopnea requiring three pillows at night, increasing attacks of cardiac asthma coming three or four nights a week, and numerous smaller hemoptyses. Two months before, he entered the hospital for ten days' treatment. Full digitalization produced slight improvement, but shortly after discharge symptoms all became more severe with marked liver pain, nausea, vomiting and the onset of jaundice. He had been unable to work for two years and had led a bed and chair life for six months.

Physical Examination There was a marked degree of jaundice, orthopnea and cyanosis. The heart was grossly enlarged with apical systolic and diastolic murmurs, rhythm grossly irregular, rate eighty. The liver was felt five cm below the costal margin and markedly tender. There were râles at both lung bases. There was no edema of the legs. Blood pressure was 120/70.

B M R level was minus four

Rationale for Operation On full digitalization and bed rest we had seen this patient grow progressively worse over a period of two months. He was totally incapacitated and very uncomfortable from his severe cardiac asthma. It was felt that operation alone might offer him some relief.

Operation August 10, 1934 Anesthesia Local Complications None

Postoperative Course Since operation now four ten months ago the patient has remained somewhat more comfortable than before but has been able to increase his activity very little. He has spent about half of the time in bed, and only on rare occasions has been able to walk out to the street. Dyspnea and palpitation have continued to be severe on any but the slightest exertion. Cardiac asthma, which had caused great discomfort several nights a week for about a year prior to operation has completely ceased except for several attacks associated with severe respiratory infection. While the B. M. R. fell to minus twenty-seven one month after operation no marked signs of myxedema appeared until the fifth month when the rate was minus thirty-five. Uncomfortable myxedema symptoms have been controlled on one quarter grain of thyroid every other day. In the fifth month symptoms of digitalis intoxication appeared on one and a half grains daily and since then the patient has been carried on five one and a half grain pills a week.

Result The patient feels that the operation has been worth while for the simple reason that cardiac asthma has ceased however he has shown no improvement otherwise and is still a cripple. Operation has doubtless prolonged his life but to what avail? In a situation of this type we cannot feel from our point of view that the procedure has been justifiable.

Comment The comment of the previous case (No 17) likewise applies here. Because of too rapid progression and too severe heart disease this patient should not have been considered favorable for operation.

CASE 19 B. R. No 337309 F Aged thirty-three. Syrian Sitcher

Diagnoses Rheumatic heart disease mitral stenosis and regurgitation aortic stenosis and regurgitation, congestive failure hypertension.

History This patient entered the hospital for the second time December 17 1934. Twenty years before she had had acute rheumatic fever. For one and a half years she had noticed increasing fatigue on exertion. Nine months previously she first had several spells of paroxysmal nocturnal dyspnea. These were followed by some increasing dyspnea and palpitation and two to three pillows were required at night. She was kept in bed for one month and digitalized. Following this, weakness and palpitation made it impossible for her to work. In May 1934 seven months before the second admission she entered the hospital for study. While there total thyroidectomy was decided on but the patient developed mumps and was discharged to return at a later date. Following another two weeks in bed at home she gradually started increasing her activity but on doing housework she had a return of palpitation and dyspnea, and had several more attacks of nocturnal dyspnea. Symptoms continued about the same up to the time of entry and she was able to be up and about but not able to carry on any work.

Physical Examination The patient was lying on two pillows in no distress. The neck veins were slightly full and pulsating. The heart was grossly enlarged to the left with sounds of poor quality. There were aortic and mitral diastolic and systolic murmurs. Blood pressure was 134/80. The lungs were clear. The liver was not felt and there was no edema.

B. M. R. level was plus twenty-five

Rationale for Operation Because of slowly progressive and incapacitating cardiac symptoms in this patient under careful medical management, it seemed wise to give her the benefit of operation. The lack of any gross congestion or rapid progression seemed favorable factors, as did the consistently high B. M. R. (It was not felt that she had any thyrotoxicosis as was later proved by histologically normal gland.)

Operation January 18 1935 Anesthesia Local

Postoperative Course Three days after operation the patient developed a positive Chvostek and Trousseau requiring calcium by mouth. The operative scar showed moderate drainage and there was some swelling in the neck. The cardiac compensation was satisfactorily maintained. Two and a half weeks following operation the patient suddenly developed what appeared to be pneumonia with some collapse in the left lung base. There were marked cyanosis and respiratory distress requiring an oxygen tent for two days. Following this there continued to be signs of congestion at the lung bases, the patient had to sleep on three to four pillows. There were marked general weakness and some edema of the sacrum and legs. On March 13 about two months following operation further signs of consolidation appeared in the left lung the temperature and pulse rose and the patient died in collapse.

Autopsy, Limited to the chest. There was no evidence of thyroid or parathyroid tissue found in the neck. The left lung showed a small area of atelectasis in the lower lobe and there was scattered pneumonic consolidation through both lungs. There was no evidence of embolus. The heart was markedly enlarged weighing 7.5 grams. The aortic valve showed thickening and nodularity. The mitral valve showed no marked abnormality although there was slight thickening of the free margins. There was evidence of chronic myocarditis with small areas of fibrosis and a few small areas of round cell infiltration. The coronary vessels were normal.

Result Because of postoperative pulmonary complications this patient was never out of bed following her operation. Doubtless aggravated by the infection, her cardiac decompensation increased.

Comment This patient should have done well, but for uncertain reasons, complications arose and she never left the hospital.

CASE 20 H. R. No 340719 M Aged twenty-eight. Native. Unemployed.

Diagnoses Rheumatic heart disease, mitral stenosis and regurgitation, aortic stenosis and regurgitation, congestive failure.

History This patient first entered the hospital October 16 1934. At the age of eleven seventeen years before he had acute rheumatic fever and for the following seven years was troubled by joint pains off and on. Following an appendectomy three years before entry he developed a severe cough with the raising of some bloody sputum and had never since been normally strong. A year and a half before entry he first experienced difficulty in breathing while at work and shortly after started having paroxysms of nocturnal dyspnea. Nine months before entry he suffered a sudden attack of dyspnea, crushing localized precordial pain and hemoptysis. He was taken to a local hospital where he was digitalized. Following this there were localized precordial pain, coming in paroxysms not related to exertion and not relieved by ultraglycerine. Marked dyspnea with hurrying on the level or go-

ing over stairs, almost constant palpitation, and a constant productive cough. He required about three pillows at night. At the time of entry he had been unable to do any work for over six months, could not go over stairs and could only walk about one quarter mile on the level.

After a period of three and a half weeks' study in the hospital, during which time total thyroidectomy was decided upon, the patient developed an acute respiratory infection and was sent home to return for operation at a later date.

January 22, 1935 the patient was readmitted. For about six weeks he had been somewhat more symptom free than before his first entry, but ten days prior to entry he had another hemoptysis and attack of severe dyspnea requiring a hypodermic and local hospitalization. After four or five days of bed rest he was again improved.

Physical Examination There was no cyanosis. The neck veins showed moderate pulsation. The heart was grossly enlarged to the left with sounds of poor quality, mitral and aortic systolic and diastolic murmurs were present. The blood pressure was 154/46. The lungs were clear, the liver edge was not felt, and there was no edema.

B M R level was minus six.

Rationale for Operation Because of symptoms largely of left sided failure without edema, it was felt that this patient should do well after thyroidectomy. He had received adequate medical care and in spite of this remained incapacitated.

Operation January 28, 1935. Anesthesia Local. The day following the operation the patient developed a small collapse at the right base which cleared promptly. There were no other complications.

Postoperative Course February 9, 1935 the patient left the hospital. Within one month his B M R dropped to minus eighteen and he gradually began to increase his activities without discomfort. He was enabled to go over stairs and within two months could walk three or four miles a day without dyspnea. He had no paroxysmal dyspnea, almost no palpitation, and only occasional mild precordial ache. At the end of three months he had a B M R of minus twenty-nine and appeared quite myxedematous, one quarter grain of thyroid every other day was started. At this time he seemed practically symptom free, slept well on one pillow and was going out trout fishing. In the fifth month he noted a distinct increase in lethargy, he was not able to concentrate or think so well as before, yet the B M R had risen to minus eighteen. He noticed a distinct increase in dyspnea on any exertion, and was requiring three to four pillows at night. An other episode of severe precordial pain, severe dyspnea and hemoptysis requiring hypodermic and local hospitalization occurred. From that time on all of his cardiac symptoms were as severe as before operation and he had the added symptoms of marked mental dullness, drowsiness, irritability and abdominal distention in spite of a B M R of minus twenty. Suddenly, about seven and a half months after his operation, the patient was seized by another severe attack of precordial pain, dyspnea and hemoptysis, and died within one hour of admission to his local hospital in spite of venesection and morphine. No autopsy was obtained.

Result For a period of three to four months following operation, this patient appeared to be remarkably improved. Then, however, symptoms returned and the patient was quite miserable, finally dying with acute pulmonary edema seven and a half months after operation. While the operation may have afforded some temporary benefit, we do not feel that it was worth while.

Comment The possibility of pulmonary thrombosis as a complicating factor in the case is to be considered as a possible explanation for the rather rapid downhill course.

CASE 21 L. H. B. M. No 8126 F Aged twenty-seven

Diagnoses Rheumatic heart disease, mitral stenosis and regurgitation, paroxysmal auricular fibrillation, congestive failure.

History The patient entered the Baker Memorial Hospital May 2, 1935 for the fifth time because of heart failure. At the ages of twelve, fourteen, and seventeen she had had attacks of acute rheumatic fever. November 1932, March 1933, and October 1933 she had been admitted because of severe attacks of paroxysmal auricular fibrillation. June 1933 the patient was in the hospital for acute appendicitis with operation successfully done under spinal anesthesia. Signs and symptoms of definite congestive failure first appeared nine months before the present entry when increasing dyspnea and edema of the legs was noted at night, and palpitation became quite constant. Eight months before entry a chronic cough set in. Four months before entry she remained in bed for six weeks and under full digitalization edema disappeared. While in bed at this time sudden pain developed in the right side of the chest and the patient coughed up several clots of blood. On resuming moderate activity edema gradually returned and increased until three weeks before entry she was again forced back to bed. For nine months she had required three to four pillows at night.

Physical Examination The patient was sitting up straight in bed. The heart was grossly enlarged to the left with apical systolic and diastolic murmurs, rhythm grossly irregular. Blood pressure was 150/80. The lungs showed slight dullness at bases (Small amount of fluid by x-ray). The liver was felt three to four cm below the costal margin. There was moderate sacral edema.

B M R level was plus fourteen.

Rationale for Operation It was felt that this patient who was able to maintain compensation at bed rest, but for whom even slight activity was too much, should be a favorable case for operation, since she was young, had no complicating factors and a plus B M R.

Operation May 13, 1935. Anesthesia Local. Complications None.

Postoperative Course At the time of discharge, three weeks after operation, B M R was minus three, heart consciousness and orthopnea were largely relieved. Two weeks after leaving the hospital the patient again began to develop edema requiring three more weeks in bed and salyrgan. For another two weeks she started to move about slowly, but again became edematous. Following that she was confined to bed with massive anasarca which could not be controlled by salyrgan up to the time of her death October 30, 1935, five and a half months after operation. About two months after operation marked coldness, swelling of eyes and lacrimation set in, making the patient uncomfortable. First one quarter grain of thyroid was given every other day, then daily and finally after about three months the dosage was raised to one half grain daily because of continued general discomfort from myxedema. B M R's were not done, but at the lowest, metabolism was judged to be about minus thirty. During the months following operation hemoptysis associated with severe chest pain occurred on several occasions.

Result The patient showed no benefit from operation and continued a rapid downhill course

Comment This patient almost certainly had pulmonary infarction which was likely in large degree responsible for her rapid downhill course. Again she showed a rapidity of progression in the two months prior to operation similar to that of cases 17 and 18 which should have made the procedure seem inadvisable.

DISCUSSION

In the treatment of hopeless, progressive cardiac disease the physician grasps at any therapy which may offer relief to his patient. Such therapy, however, must offer more than the prolongation of life for a few weeks or months of distressful existence. Our experience with total ablation of the thyroid gland in the treatment of congestive heart failure seems to show that a certain prolongation of life was all that we had accomplished in some cases. In others, however, striking symptomatic benefit was obtained.

The trial of the procedure was designed to give us a point of view concerning this therapy as it could be developed in a general hospital for it is doubtful if any method of treatment can become of far reaching application that cannot be administered in any well integrated hospital.

It is in the problem of the selection of cases and the unpredictability of results in the individual case that the great obstacle to the recommendation of the operation lies. The list of contraindications to the operation has been given and attention to this in our clinic has finally resulted in a classification of cardiac patients in which all but a very small group are considered unsuitable for the procedure. It is extremely difficult to select a patient who on the one hand is not too sick to be benefited by operation, or on the other hand so relatively well that the physician may entertain fears lest the operation which he recommends may leave his patient worse than before. He must realize that, generally speaking, failure to relieve the patient by operation results in leaving on the physician's hands not only a cardiac problem, but also one of avoiding the discomforts peculiar to myxedema. Theoretically it should be easy by means of a small dose of thyroid, to avoid the symptoms of myxedema. In actual practice, however, it has been our experience that even when the metabolic rate is maintained at levels where gross manifestations of myxedema are absent, there may yet remain certain unpleasant symptoms fairly attributable to the low metabolic rate. Even here nice adjustment of thyroid dosage may overcome the difficulties.

It is significant that while we have not abandoned this procedure, with the large number of cardiac patients seen on the wards in the past

six months, in no case have we felt sufficiently confident to recommend the operation.

Our results in congestive failure indicate that in cases well selected and managed, worth while results may be expected in about half. With this in view, in a suitable case, it is for the physician and for the patient to decide whether a procedure of this magnitude, carrying with it certain discomforts and certain risks, is worth while for a temporary improvement in the course of an inevitably fatal disease. This is a point where individual philosophy must enter the picture.

Concerning the results in angina pectoris our series does not warrant the drawing of conclusions. In one of the two cases the effect of total thyroidectomy has been definitely beneficial. In our clinic intractable angina pectoris is more frequently treated by paravertebral alcohol injection than by thyroidectomy.

Recent figures from the Beth Israel Hospital, Boston, where the greatest amount of this work has been done, based on patients operated upon from one and a half to three years ago show the following results which are somewhat more favorable than ours:

TABLE 7

	Congestive Failure	Angina Pectoris
Great Improvement	13 (35%)	18 (50%)
Moderate Improvement	10 (29%)	6 (17%)
Slight Improvement	7 (21%)	7 (19%)
No Significant Improvement	5 (15%)	5 (14%)
Total	34 Cases	35 Cases

In addition to the cases listed above there were six operative deaths. We may reasonably assume that the cases showing "Great and Moderate Improvement" were worth while. This gives 64 per cent in the congestive failure cases and 67 per cent in the angina cases. Were the six operative deaths included in this table under "No Improvement" as in our table 4 the net results would be slightly lower.

From the Peter Bent Brigham Hospital, Boston the other hospital in which this work was started, we are given the following results based

TABLE 8

CONGESTIVE FAILURE 25 CASES	
Great Improvement	6
Moderate Improvement	5
Slight Improvement	2
No Improvement	12 (2 operative deaths)
ANGINA PECTORIS 29 CASES	
Great Improvement	11
Moderate Improvement	10
Slight Improvement	4
No Improvement	4 (2 operative deaths)

on cases operated upon from three years up to one year ago⁶. During the past year only three total thyroidectomies for heart disease have been done.

Three of the above cases were classified under both angina and congestive failure. These figures include the early cases operated on which were desperately sick and later realized to have had too severe heart disease to have been properly chosen for operation. In this series a case was considered a good result if physiological cardiac improvement occurred, as the case of a patient with angina having daily pain before operation and none for two weeks after operation but dying at the end of that time with a coronary occlusion, yet, as in this case, the patient might be classified as not showing a worth while result when the case is considered as a whole.

If further investigations permit more precise recognition of the criteria for the selection of cases and can give the profession a greater assurance of favorable results than it has at present, then certainly this form of treatment may be considered worth while.

CONCLUSIONS

1 We are reporting the results of total ablation of the thyroid gland in twenty-one cardiac patients operated on at the Massachusetts General Hospital between July, 1933 and May 1935. Nineteen patients had congestive failure and two had angina pectoris. Our conclusions are, therefore, based almost wholly on our experience with congestive failure.

2 Fifteen patients are now dead. In about one-fourth of the entire series the operation was considered worth while, in three-fourths it was not.

3 The relatively poor results in our series depend to a considerable degree upon the dif-

ficulty in selection of cases and in the fact that too severe cases were originally chosen. The contraindications to operation are numerous, but in cases well selected and handled, worth while results were secured, at least temporarily, in fifty per cent.

4 There is a small group of patients with cardiac failure in whom medical therapy is ineffective in controlling the progressive loss of cardiac reserve for whom total thyroidectomy offers an even chance of worth while improvement.

5 Avoidance of the grosser manifestations of myxedema we have not found difficult. Small daily rations of thyroid usually accomplish this purpose. In some cases, however, at a metabolic level above that of complete myxedema, low rate symptoms have been troublesome.

6 It is our belief that the procedure must be further studied before its usefulness in the treatment of heart disease can be fairly evaluated.

We are indebted to Dr H L Blumgart for frequent advice and suggestions in the course of this study.

MEDICAL AFFAIRS IN CONNECTION WITH THE CALIFORNIA PACIFIC INTERNATIONAL EXPOSITION

Tuesday, May 26, has been designated as California Medical Association Day at the 1936 California Pacific International Exposition, San Diego, which opened February 12 and will continue to September 9.

Approximately 3,000 physicians and their families are expected to visit the world's fair in Balboa Park upon that occasion.

The focal point of the conclave will be the Palace of Medical Science, one of the principal exhibit palaces of the 1936 exposition, where extensive displays will be sponsored by the leading medical societies and manufacturers of pharmaceutical supplies.

A program appropriate to the day is being arranged by an exposition committee of the San Diego County Medical Society, with Dr Lyell C Kinney,

1831 Fourth Avenue, San Diego, acting as chairman. Direct cooperation is being lent by Dr Ben F Eager, Medico-Dental Building, San Diego, president, and Dr W C Crabtree, Medico-Dental Building, San Diego, secretary of the San Diego county society.

A medical exhibit in the Palace of Medical Science will be sponsored by the San Diego County Medical Society with the cooperation of the California Medical Association and the American Medical Association. Dr W H Geistweit, Jr, of San Diego, has been named director of medical exhibits to arrange details of this exhibit.

It is predicted that the medical exhibits at the 1936 exposition will be the most extensive yet displayed. The whole Palace of Medical Science will be devoted solely to exhibits treating on the prevention and treatment of disease, and it will form one of the important features of this world's fair which is dedicated to mankind's progress in all realms of science, art and industry.

NEW ENGLAND SURGICAL SOCIETY

THE CONTRIBUTION OF THE COMMUNITY HOSPITAL
TO BETTER MEDICAL SERVICE*

BY PETER P. JOHNSON, M.D.†

WHEN we compare the limited field of medicine of the "horse and buggy" days with the great progress of the present the question arises as to whether the application of our art has kept up with its development. In the opinion of many it has not. Perhaps one of the most serious criticisms is that economic factors prevent a large proportion of our population from receiving suitable medical care. Other criticisms relate to free competition the sliding scale, fee splitting, the "appalling incompetence of the family doctor, too much surgery and the inability of the public to determine the qualifications of the doctor.

As a means of overcoming the economic difficulties, group practice or state medicine financed by taxation or insurance, either voluntary or compulsory, has been suggested. As a solution group medicine may offer interesting possibilities of decreasing slightly the cost of medical care, but one can conceive of its being applicable to only a small number of communities. Even so, the quality of its service would naturally depend on the type of individuals making up the group. The incompetent would still be incompetent, the fee-splitter would still be a fee-splitter and group competition would merely be substituted for that of the individual.

State medicine would undoubtedly provide medical care at a lower cost, but it is hard to understand by what magic it would improve the quality. Nothing in the experience of the countries which have adopted this form of medical practice suggests that a higher type of service is given. With the great amount of free service provided by doctors, hospitals and communities, it is difficult to believe that in New England there is much suffering because of the lack of adequate medical care.

It is unnecessary to elaborate to any degree upon the economic aspect of this subject for it is one which has been discussed in the lay and medical press, as well as in every recent medical meeting. The problem does exist and it behooves us to familiarize ourselves with its details and to give it our sympathetic consideration and cooperation to the end that the best interests of the patient and the doctor may be served.

Whatever solution is evolved, the medical aspects of the problem should be under the con-

trol of physicians and absolutely free from the domination of politics or of any organization operating for profit.

Most of the criticism emanates from economists, sociologists and committees investigating the cost of medical care and this latter group seems to be made up of men who have but little professional contact with the so called low income group. There is, on the other hand, no great evidence that the public itself is particularly dissatisfied with the quality of the service which it receives. An enlightened public can demand through its legislature as it does not in Massachusetts that only properly qualified physicians shall be permitted to take examinations for licensure, that those desiring to specialize shall give evidence of fitness and suitable training, and, further, if so desired, that some form of examinations be held at reasonable intervals to test their competency and their right to continue in practice. These are matters over which the medical profession itself has no control. Even attempts on the part of our medical societies to discipline their members who are guilty of unethical practices raised the cry of oppression at the hands of organized medicine. Any attempts on our part to elevate the standards meet with immediate opposition. To relieve our profession of a source of serious and just criticism, some method is needed by which the fee-splitter, the man who operates for the fee alone and the hopelessly incompetent can be eliminated.

While we may not yet have a satisfactory solution for the economic situation, there is still much that we, and the hospitals with which we are connected can do to improve the quality of both medical and surgical practice.

At present the general practitioner finds himself between the devil and the deep blue sea. By some he is told that he should be able to diagnose and care for from eight to ninety per cent of all illness, while by others that his incapacity is so great that he must give way to a new order. It is true that our changing economic life has placed him at a great disadvantage, and it is equally true that many of the newer diagnostic measures may be beyond his power to perform. The value and importance of these measures can certainly be understood by him and the indications for their application recognized. As with most of us, the mistakes which he makes are not so much due to his failure to make use of this bewildering array of diagnostic aids as to his failure to take careful

*President. Address delivered at the Annual Meeting of the New England Surgical Society at Manchester, N. H. September 7, 1935.

†Johnson, Peter P.—Chief of Surgical Service, Bay State Hospital. For record and address of author see "This Week's Issue," page 179.

histories and make careful examinations and carefully coordinate his findings. The tendency of the day is to rush for the diagnosis to the x-ray and the laboratory, aids which in a goodly percentage of cases should be merely confirmatory and supplementary.

I believe that the general practitioner is not so incompetent as his critics claim. I feel sure that he today gives a higher grade of careful, devoted, intelligent and self-sacrificing service than ever before. Whatever his shortcomings, it is obvious that he will still be in demand for long years to come. To what other agency could the acutely ill turn for relief? He should be the first to be consulted. His care may not necessarily, as of old, include the whole family, and it is quite probable that many of his patients will, and often to their disadvantage, consult specialists of their own selection.

In the smaller cities and communities, the hospital should provide him with the facilities for obtaining the various laboratory investigations and specialized assistance in the care of his patients, and thus at a reasonable cost. Further, the hospital should provide him, if competent and ethical, with a place where he may treat his private patients. On the other hand, the hospital should limit the doctor to the type of work for which he is fitted by training and experience and should compel him to observe its high standards, so that a patient who enters its doors, whether charity or pay, shall know that he will be in competent hands. It is true that opening the doors of the hospital to larger numbers of doctors will complicate the administrative problem, but the benefits to both the doctor and the patient will far outweigh its disadvantages.

The great need of the physician is the continuance of his medical education in order that he may keep fully abreast of the times, and his failure to accomplish this is undoubtedly the principal cause of criticisms directed against him. As a rule, postgraduate medical education is available only by trips away from home and the expenditure of time which it is difficult to give.* Yet the hospital of his community contains an abundance of clinical material which could be used for teaching purposes. Hospitals have contented themselves with the care of the sick and the training of nurses but, from an educational point of view, have neglected their opportunities to be of service to the profession as a whole. The physician who feels that he cannot go away for postgraduate instruction will benefit as much by spending an hour or two

each week in the hospital of his neighborhood. In this way he will not only get an opportunity to see a greater variety of cases than he would daily meet, but will come in closer contact with his fellow practitioners.

Firmly convinced of the value of this postgraduate teaching, we have, in our hospital, made available to the family doctor all our facilities, including autopsies. Many years ago we instituted a weekly operative clinic, but later changed to a monthly medical and surgical clinic followed by luncheon. That these clinics are considered of value is attested by the fact that there is usually an attendance of some thirty or forty physicians, that luncheon is not the principal inducement is evidenced by the fact that but a small number remain for it. More recently, in addition to the monthly clinic and the regular staff meeting, there has been instituted a weekly ward visit, followed two days later by an operative clinic. Rather than the usual perfunctory ward visit we have tried to make this a ward clinic, at which a small number of instructive cases are considered. Each one of these is turned over to a physician, who is told as briefly as possible the reasons for which the patient sought relief and is supplied with whatever information he desires as to the history, examination and laboratory findings. He is requested to discuss the case from the point of view of diagnosis and treatment, after which the whole group is encouraged to take part in the discussion. At the operative clinic, patients seen in the ward and requiring operation are presented, so that physicians interested may not only have a hand in the diagnosis but also see it verified or disproved, and at their subsequent visits observe the outcome.

Whether or not this employment of clinical instruction is the cause, it is rare indeed for a serious surgical emergency to be received from the hands of the family physician too late for operative relief. The signs of cancer are more early recognized and cases of perforated appendix have become less frequent. So suspicious has the doctor become of acute abdominal pain that only one in three of the patients entering the hospital with a diagnosis of acute appendicitis is such, and requires operation. This is, at least, a much safer course of action than the former one of procrastination.

Such clinics require leadership, time and effort, but the benefits derived are well worth the effort, for unconsciously the standards of the profession and of the hospital will be raised to the profit of the community.

The general practitioner and general surgeon are the offspring of the old family doctor. Their interests are identical. The diagnostic skill of the general practitioner determines in a large measure our surgical results. It is, therefore, our duty as a surgical organization to

*In Massachusetts under the auspices of the Massachusetts Medical Society postgraduate study has been furthered by courses of lectures given throughout the various districts by qualified specialists. The attendance at these lectures indicates that many physicians are anxious to take advantage of the opportunities for further study. The value of this method would be greatly increased if it could be combined with the use of clinical material.

work for the betterment not only of the surgeon but of the general practitioner, of whom Sigerist, in his preface to "The Great Doctors" has fittingly said "Bach and Mozart would be dead for ever, were it not for the living artists who are perpetually reviving their melodies. Pasteur and Koch would have lived in vain but for the everyday practitioners through whose activities their teachings are made effective. It is not so much the great theoreticians upon whom the health of the community depends, as the huge army of family doctors who sneer the ailing from hour to hour.

Surgery should certainly be practised only by those thoroughly trained in the art. Our first President, Doctor Mixter, in his presidential address, speaking of the surgeon said "It must be strongly emphasized that the surgeon is not born but made. Thorough training of the mind and hand, hospital experience under the control of able masters—these are the absolute essentials and should be insisted on in the future as they have not been in the past.

What Doctor Mixter said nineteen years ago is even more true today. With the further advances in surgery the general surgeon's field of activity has been broadened and he therefore requires an even longer and more thorough period of training. Under our present system this necessary training has been acquired chiefly by the surgeons who practice in the large cities, but, unfortunately, the same high standards do not prevail in the smaller communities. Surgery here is too often done by the occasional operator whose preliminary training, in many cases, has consisted only of one year's internship in some small hospital and possibly some few months of postgraduate study. The surgical material of these communities is divided among so many men who feel qualified to do surgery that no one has an opportunity to acquire the judgment, diagnostic skill, dexterity, speed and confidence that the best interests of his patient demand. In other words there are too many men doing surgery and too few real surgeons. Our present system develops mediocrity in many rather than ability in a few. It is fair to say that where now a dozen or more men do the surgical work of a small hospital, two or three thoroughly trained surgeons with a competent house staff could, to the advantage of the community, do it better. For it is a well recognized truth that as a surgeon's experience increases, not only his mortality but his morbidity rate decreases. But how will he acquire this experience if he is not kept constantly employed?

There are in New England some 300 hospitals. In twelve small hospitals taken at random, there were 14,290 operations done last year. In some of these, treating from 1500 to 3000 patients, the operations were done by fifteen or more operators. In one alone with less than

1500, fourteen men did 300 major operations. And such a proportion is probably the rule rather than the exception in a large number of these institutions. In two of these hospitals studied twenty per cent of the operations were appendectomies, and both hospitals had large surgical staffs. They removed three times as many appendices as another hospital treating the same number of patients but with a surgical staff limited to three. Using these figures on the appendix alone, would it not be logical to consider that decreasing the number of surgeons would decrease the number of unnecessary operations?

Although this organ is a potential source of danger, it is not the cause of every acute belly ache and its needless removal is hardly warranted. In spite of its advances surgery has not reached that stage of perfection where the abdomen can be opened without risk. Except under the most unusual circumstances, I do not feel able to agree with the statement of Dean Lewis that the general practitioner should do his own appendectomies. And as a reason one need only reflect on the difficulties in diagnosing an obscure case of this disease as well as the complex problems with which he must often deal when operating for what at the outset appears to be a typical case of appendicitis.

Another factor of equal importance in preventing the development of the general surgeon is the length of his hospital service. Such services are often for one, two to rarely more than three months. One small hospital in the above list has four members on its surgical staff who serve in rotation through the year of periods of one month. They hardly become acquainted with their patients or get their stride before they pass off the scene. No one can possibly conceive that under such a scheme the patient will get the highest type of care. In hospitals with services of two or three months, the surgeon is left unemployed for the remainder of the year except for such private work as may come his way. If he happens to have a large surgical practice such an arrangement is of no detriment, but it constitutes a serious letdown for the young surgeon. As a result of this his surgical development is definitely retarded to the disadvantage of his community. In practically no other important line of endeavor would one expect to reach a high degree of excellence with such limited opportunities.

In this matter of length of service there seems to be a unanimity of opinion, but little effort is made to alter the situation. The problem has been discussed with many surgeons, and with but one exception all have held the opinion that a much longer period of hospital service, or even better, a continuous service would be the ideal arrangement. All agreed that rapid turnovers

were bad for the patient and that their own judgment and skill were greater at the end than at the beginning of their services. Their opinions might be summed up in that of one surgeon who wrote "I feel that the longer the service the better. I should consider it ideal to have the service continue the year round but with enough men on duty to divide the work without its being an excessive burden on any individual. Personally, I am on a two-months' service. At the end of the two months I feel relatively quite competent. During the ten months off duty I feel that I am getting rusty, with a rust that cannot be readily polished off even by visiting other clinics. As far as physical ability to stand the gaff is concerned, I feel again that a longer period of less strenuous activity is less fatiguing than a short, overburdened one. From what observation I have been able to make, the best surgery is done in hospitals with longer services." From the very nature of things, the accomplishment of this ideal implies the division of surgery among a smaller number of surgeons.

As the surgical standards of the community hospitals are raised, there will be less necessity for patients to go to the large medical centers, often not only a hardship to them and their families, but an increased expense. The peripatetic surgeon, too, except in the rare and more difficult cases, will find himself less needed. His position at best cannot be entirely satisfactory either to himself or to the patient. Unable, owing to the distance from his base, to conduct a period of observation, he often feels compelled to operate when it would be wiser to wait. Under the most favorable circumstances he is obliged to leave the postoperative care to the local physician who may or may not be able to carry the patient through a stormy convalescence.

Because all surgery is done there, the hospital is the only organization which can limit the physician to the field for which by training he is qualified. Its surgical staff should be selected only on the basis of training and ability and in a number sufficient to the surgical needs of the community. Certainly the staff should be small enough to give each man an opportunity to maintain a high degree of excellence.

If the objection to this is that it limits free competition in the surgical field, the answer is that the interest of the patient is paramount.

If a limited number of surgeons can reduce the mortality, morbidity and unnecessary operations, with the resulting economic consequences, no further argument is needed. There is no justification for allowing everyone, who so desires, to do surgery. The amount of surgery is of necessity limited, and if, by confining the field to a few well-trained men, the results are better, the personal desires of the many must be sacrificed. Probably the one factor which, more than anything else, keeps the highly trained young surgeon in the big city is the knowledge that he will be unable to find a field in the smaller community and will have to content himself with general practice as a means of livelihood, while his surgery becomes a side issue.

It may well be that at some future date, for the best interests of the patient and the hospital, surgery will be limited to a small staff on an adequate salary. These men would give their full time to the hospital and would be relieved of the unpleasant duty of collecting fees from the patient. Under such circumstances the reasons for fee-splitting, unnecessary operations and operations for the fee alone would be removed.

Hospitals have been willing to spend large sums of money for buildings and equipment but too little for human material. Here is an opportunity to make use of that great army of well-trained young doctors who are unemployed and crowding the big cities. They could be utilized as the resident house staff without which no hospital, however small, can really operate at its highest efficiency. This association with young men, fresh from the schools and hospitals, would be of mutual advantage. It would stimulate the older men to keep up-to-date, while it would provide the younger men with many of the practical aspects of our art with which they are still too unfamiliar.

For our small communities the hospital should be the center of medical activity. With well-equipped laboratories, providing service at a reasonable cost, with a well-trained staff under intelligent leadership, with its doors open to the competent and ethical general practitioner for the treatment of his patients, it would provide a satisfactory substitute for group medicine in which the doctor would not lose his individuality, and would answer the public's question of how to obtain a competent physician.

EMOTION AND DIARRHEA*

BY ALBERT J. SULLIVAN, M.D.†

THE purging effect of strong emotion has been recognized for centuries. In this paper the early medical views on simple diarrhea are reviewed, observations from the literature on this psychomotor phenomenon are presented and recent work on the etiological relationship of emotion to certain diarrheas, usually considered organic in origin, is discussed. A plea is made for more thorough investigation of this 'no man's land', the field of psychosomatic relationships.

NERVOUS DIARRHEA

Alvarez, in his excellent book on *Nervous Indigestion*,¹ considers the ways in which emotion can affect the gastrointestinal tract. He reminds us that references to the purging effect of fear or anxiety may be found as early as 700 B.C. when Sennacherib, in describing his battle with two young kings of Elam, noted that, 'Like young captured birds they lost courage. With their urine they defiled their chariots and let fall their excrements.' In Genesis 43:30 we read that, 'Joseph made haste for his bowels did yearn upon his brother, and he sought where to weep.' In Caxton's edition of Aesop's Fables is found, 'The wolf shate thryce for the grete fere that he had.' So well known is the direct association of strong emotion and defecation that many references to it can be found in folklore and in various profane authors both classic and modern.

The scientific interest of the medical profession in this phenomenon seems to have appeared at a much later date. Sydenham² in his *Epistolarly Dissertation* in 1682 wrote 'Hysteria on the stomach will create continued vomiting on the bowels, diarrhea.' The effect of the psyche on the colon seems to have concerned Van Swieten³ for among other cases he cites this one: 'I have seen a man who had taken a sufficiently nauseating draught, not only shudder and be nauseated, but also he frequently purged when he merely saw the cup in which he had taken the medicine.' In the medical literature of the nineteenth century there are many references to the effect of mental states on the bowels particularly the purging effects of placebos and bread pills when they were considered by the patients to be cathartics. Tuke⁴ cites two interesting examples of the effect of the imagination

on the intestinal canal and adds his own amusing comment:

"In the 'Bibliothèque choisie de Médecine' is a good example of the effect produced by the Imagination, during sleep upon the action of the intestines. The daughter of the Hanoverian Consul aged 18, having to take a rhubarb purge on the following day which she especially disliked, dreamed that she had taken the hated dose. Gripped by her imaginary rhubarb she awoke, and the bowels acted freely five or six times. Precisely similar is a case which I give on the same authority (Demangeon) that of a monk for whom some purgative had been prepared, to be taken on the following day. He dreamed that he swallowed the medicine, the consequence of which was that he was aroused by the necessity of attending to the calls of nature and was copiously purged eight times. All must admit that any medical man who would engage to insure the same operations from imaginary as from real rhubarb or senna would enjoy a fashionable purgative practice."

About the middle of the nineteenth century the relationship between emotion and diarrhea received general recognition by the medical profession and nervous diarrhea became an accepted diagnosis. Hershon⁵, in 1857 listed ten causes of diarrhea, the ninth in the list being "Marked agitation or fright." John Chapman⁶ in 1866 devoted a whole chapter to "Diarrhoea Originated by the Mind." The following paragraph is quoted verbatim from that chapter:

"The following facts I am able to authenticate (1) A woman who has a drunken husband suffers great anxiety when he is away from home especially if late at night, lest anything should happen to him, and particularly lest by a fall or other accident he should receive bodily harm. This anxiety brings on diarrhoea accompanied with trembling pallor, and a peculiar haggardness of countenance.

"(2) A lady who while crossing the Atlantic suffered fearfully from sea sickness and violent diarrhoea during the whole passage has since her marriage been troubled with diarrhoea almost always when she has experienced painful emotions. On almost every occasion when her husband is unkind to her, as he is wont to be, she has a violent attack of diarrhoea."

From the Department of Internal Medicine, Yale University School of Medicine, New Haven, Conn.
Read before the National Society for the Advancement of Gastroenterology, New York, October 3, 1935.
† Dr. Albert J. Sullivan, Associate Clinical Professor of Medicine, Yale University School of Medicine. For record and address of author see "This Week's Issue," page 325.

"(3) A woman who suffers from diarrhoea whenever her feelings are vehemently excited, even although the excitement may be one of sudden pleasure

"(4) One of my patients, who was reading George Eliot's noble work 'Romola,' assured me that the emotions it excited in her brought on diarrhoeas. In fact, owing to this remarkable transformation of emotions into 'motions', she was obliged to abstain from reading the book for a time

"(5) A lady, one of my patients, when affected by any violent emotion, especially if of a distressing character, is almost immediately attacked with diarrhoea, or vomiting, or both

"(6) A gentleman, one of my patients, already mentioned, always finds himself attacked with diarrhoea after he has experienced any considerable mental excitement. It is well known, moreover, that many soldiers especially young ones, are attacked with diarrhoea when going into action "

Such a remarkable series of cases indicate that Chapman was years ahead of his time in the investigation of psychosomatic relationships. Unfortunately, most of his work was soon forgotten because of his peculiar therapeutic notions. He insisted that not only diarrhoea and cholera but also epilepsy, paralysis, uterine affections and seasickness would be cured by the application of his special spinal icebags which was the "only available power of subduing hyperaemia of the automatic nervous centres". Today he might be considered a quack but it is rather interesting that he secured a high percentage of cures in a series of diseases which are frequently psychic or functional by a method which was probably effective because of its strong psychotherapeutic appeal.

Although all this material and much more, was available in the literature, many of the standard medical works of the nineteenth century and even later dates make no mention of nervous diarrhoea. Neither Bennett's "Clinical Lectures" nor Ziemssen's 16 volume "Cyclopaedia of the Practice of Medicine" mention the subject. On the other hand, Trousseau⁶, the great French clinician, devotes much space to the discussion of this form of diarrhoea. He says, "It was necessary, Gentlemen, that I should enter into these details, because nervous diarrhoea is one of the most frequent forms of the affection, and is at the same time one of those in which the physician can be most useful, when he knows how to recognize it "

Toward the end of the nineteenth century, the concept of nervous diarrhoea began to be widely recognized. In the first (1892) edition of Osler's "Practice of Medicine" we find the following discussion

"It is by no means clear how mental states act upon the bowels, and yet it is an old and trustworthy observation which everyday experience confirms that the mental state may profoundly affect the intestinal canal. These influences should not properly be considered under catarrhal processes, as they result simply from increased peristalsis or increased secretion, and are usually described under the heading nervous diarrhoea. In children it frequently follows fright. It is common, too, in adults as a result of emotional disturbances. Constatt mentions a surgeon who always before an important operation had watery diarrhoea. In hysterical women it is seen as an occasional occurrence, due to transient excitement, or as a chronic, protracted diarrhoea which may last for months or even years "

Inasmuch as this discussion concerns only the clinical aspects of the problem, I shall not attempt to review the work of modern investigators such as Cannon and Alvarez to whom we owe so much for their important physiological investigations in this field. An excellent concise review of the literature on psychic influencing of gastrointestinal secretion and motility is given by Alvarez⁸.

ORGANIC DIARRHEAS

So far we have considered diarrhoea only as a symptom of emotional episodes. None of the group of diarrheas commonly called "organic" have been considered. In the foregoing quotations the close association between cause and effect (the emotion and the diarrhoea) has not escaped the physician and the diagnosis of nervous diarrhoea was fairly obvious. The diarrhoea was short and lasted for the duration of the emotion (usually fear or anxiety). When presented with a case of chronic diarrhoea lasting one or more years, the true relationship between cause and effect was blurred and it is easy to see how possible emotional origins were rarely traced. A chronic diarrhoea is rarely painless, as long-continued irritation results in other symptoms referable to the colon. It thus takes on the aspect of an "organic" disease. When the physician can find blood, pus or mucous casts in the stools and the patient exhibits constitutional signs of organic disease such as fever and leukocytosis, it is almost impossible for the organically-minded physician to realize that an emotional episode may have initiated the "disease" no matter how distant its beginning, or that chronic emotional disturbances may have been responsible for the chronic diarrhoea.

Before we consider the early historical references concerning the effect of emotion on so-called "organic" diarrheas it is well to discuss briefly the rough classification of organic diar-

rehearsals as they were described in the middle of the last century. Most diarrheas characterized by bloody stools (whether they occurred in epidemics) were called dysenteries. Epidemics of cholera were seen, even in England. However sporadic cases of diarrhea, especially if sudden in onset, with copious liquid stools and accompanied by fever and vomiting were nearly always diagnosed as cholera. The chronic diarrhea associated with pulmonary tuberculosis was usually recognized as tuberculous enteritis. Mucous colitis had been described under a variety of names. Ulcerative colitis was first described by Wilks in 1869.⁹ This description was amplified by Wilks and Moxon in 1875¹⁰ and by White in 1888.¹¹ However, in the earlier literature undoubted cases of this disease can be found under the name of "simple intermittent dysentery."¹² It is interesting in view of our present idea that the disease is psychic in origin to find that one of the earlier synonyms for the disease was "anxiety dysentery."

It is, of course, confusing to find the terms diarrhea, dysentery and cholera used almost synonymously, therefore certain reservations must thus be made in the interpretation of some of the quotations which will be mentioned.

The earliest reference I have been able to find indicating that emotion may initiate an "or game" diarrhea is in Habersham.¹³ In chapter 10, "On Colitis and Dysentery" he reminds the reader that "the depressing effect of night watching, and of witnessing the rapidly fatal termination of the disease, tends also to induce the complaint." Chapman¹⁴ in his discussion of the causes of cholera writes as follows:

"That fear, fright, and panic are fruitful sources of cholera is attested by a large number of authoritative witnesses. There is an old, and often repeated story of an encounter outside an Eastern city between the plague demon, when about to enter the city, and a citizen who asked what he was going to do there, and who was told by the demon that he was going to kill 3000 people. On his return from the city, the same citizen taxed him with lying, inasmuch as 30,000 had been killed. True, said the demon, but I only killed 3000, fear killed the rest." This story contains a great truth which is recognized by almost every observer of a cholera epidemic. Referring to the last epidemic in Turkey, Mr. Harry Leach says, 'Panic undoubtedly increased its intensity in many instances and brought cases of simple diarrhoea into the grip of cholera very speedily indeed.' Drs. Bell and Stokes remark, 'many have been destroyed by fear alone', and Dr. Wood says, 'Sudden and strong emotions, often bring on an attack.' Dr. Macpherson observes,

"Cholera attacks all who are to be seized, and confidence seems to be of use both in warding off an attack and in struggling through it. The excessive alarms during epidemics are most injurious." Dr. Mac Cormack says he can assert from personal experience that "fear alone will produce the disease", and makes the following statement (often made also by others) for which however he gives no authority. 'In the year 1832, a man was unfortunately tempted, by a large sum, to occupy for a certain time a bed in which he was informed a cholera patient had died and although such had not been the case, he nevertheless from pure fear, was in a very short time seized with the symptoms of cholera and died.' Dr. Forbes Winslow pitifully remarks, "During an attack of cholera, the patient who has the least fear of dying has, ceteris paribus, the best chance of living."

Take¹⁵ gives us several more examples of the emotional origin of 'cholera'.

"The story of the Russian convicts under sentence of death, some of whom were placed in beds falsely said to have been occupied by cholera patients, will occur to the reader. Mr. G. Smith reported in the *Lancet* of August 4 1866, the case of a fine hale blacksmith under surgical treatment in King's College Hospital, who carried down the bed on which a cholera patient had died. He sat up until late brooding over what he had done and its probable consequences. He died next morning of cholera. Those, however, who believe that cholera is contagious would not admit that, in this case Fear was more than the exciting cause of the attack.

"When, some years ago, the cholera was prevalent at Newlyn, a fishing village near Penzance intercourse was forbidden between the two places. One day a man entered the shop of a barber in Penzance and was shaved. On leaving, some one, who had recognized him, asked the barber if he knew whom he had been shaving. He replied he did not. 'Why, he's a man from Newlyn!' It was enough. The terrified barber was seized with cholera, and died within twenty-four hours.

"Mr. of Falmouth some years ago had the cholera. When well he went to the Lizard for a change. The woman who opened the door of the house to which he went having heard that he had had the cholera was exceedingly alarmed, and had an attack herself."

MUCOUS COLITIS

The foregoing material has, I believe indicated two things: (1) that hyperactivity of

the gastrointestinal tract as expressed by diarrhea is frequently the result of certain strong emotions and that it has been recognized by laymen and physicians for many years, and (2) that certain physicians have felt for nearly a century that occasionally strong emotion was the precipitating factor in certain cases of diarrhea ordinarily considered "organic"

How have we, as physicians, made use of these two concepts? The first, that of nervous diarrhea, has received general recognition. Most of us, who have had classmates seized with severe diarrhea at examination time or have had comrades in the trenches so affected before going "over the top", have remembered in our practice that there was such a syndrome as nervous diarrhea. All too often, however, it has been a diagnosis by exclusion after we had vainly searched for all other possible causes, or perhaps the correct diagnosis has been presented to us by the patient who insisted that it was "just nerves". Not very often do we search for emotional disturbances in our patient's life as systematically and conscientiously as we do for amebae in his stools.

The second concept, that emotion may be responsible for initiating an "organic" diarrhea, has been almost completely ignored. Let us consider that syndrome which is usually spoken of as mucous colitis. The term is a misnomer, of course, for "mucus" in the stools is not invariably present nor necessarily a prominent feature nor is "colitis" applicable since there is ordinarily no inflammation of the colon. It is not a true diarrheal disease since constipation is, at times, a prominent feature. However, it serves well to illustrate a few points that deserve emphasis.

I will not go into the historical aspects of the disease (which are of interest chiefly because of the thirty-five different names which have been applied to it) other than to state that it had been thoroughly investigated and described by American clinicians long before it received the critical consideration of foreign physicians. It was first described by Mason Good¹³ as "Diarrhoea Tubularis—Tubular Looseness."

In discussing mucous colitis, Osler⁷ writes, "The cases are almost invariably seen in nervous or hysterical women or in men with neurasthenia. Mental emotions and worry of any sort seem particularly apt to bring on an attack. In mucous colitis no benefit can be expected from remedies administered by the mouth. The general nervous condition should receive appropriate treatment."

Since that time many writers have expressed similar opinions. However, the "organicists" die hard. In one of the leading textbooks¹⁴ of medicine of today, we read, "Mucous colitis was formerly regarded as a neurosis, but clinical and pathological observations now justify

the conclusion that it is a form of chronic colitis." Yet the description of the disease continues in these terms: "It frequently, though not invariably, occurs in patients with enteroptosis. Spastic constipation is always an accompaniment, it is far more common among women than men, and the sufferers are often highly neurotic!"

Here is a syndrome suspected for years by medical men, of being emotional in origin yet rarely treated as such. Practically the only thorough case reports are in the psychiatric literature. The articles by medical men are largely attempts to prove a bacterial, an allergic or a deficiency origin of the disease. It is amusing (or rather, tragic) to note how often such a study is prefaced by the remark "in an attempt to place this disease on a scientific basis." Many commendable attempts at the study of this syndrome have stalled at the halfway mark and "neurogenic colopathy" has been added to our terminology. Our old friend "vagus" and "sympatheticotonia" are used to explain the syndrome. Just because emotions make use of the vagal and sympathetic nerve pathways, does a syndrome become "neurogenic" instead of "psychogenic"?

Our insistence on finding an organ (the "soma" as opposed to the "psyche") on which to pin the cause of a syndrome has led us astray before. If we are to be consistent, now that the autonomic nerve centers have been discovered in the diencephalon, we should discard vagotonia and sympatheticotonia and speak of "diencephalonopathy." But if it is discovered that the pituitary gland is the activating agent of these centers we are then back on the trail again, tracking down adrenals, thyroid and gonads. We must not forget the merry chase we have had to find the organ responsible for diabetes.¹⁵ First the kidney was responsible for spilling sugar, then Bernard's sugar puncture gave us a localistic neurogenic concept, then Mehring and Minkowski with extirpation experiments shifted us to the pancreas. Banting and Best reinforced this concept, but soon it was obvious that liver, muscles and other organs were involved. Recent investigations show that a depancreatized animal can live if the pituitary is also removed. Has the trail only led us back to the neurogenic concept of Claude Bernard? Remember that in this disease, also, there have been many who have thought that occasionally the disease was psychogenic.

And to return to our unfortunate patients with mucous colitis, how do they fare? Teeth, tonsils, appendix, and gallbladder are removed as foci of infection. Prostate and tubes are under suspicion. Bacterial flora are subjected to cultivation by a form of intestinal gardening. A belt or even an operation for a mobile cecum or ptosed transverse colon may be advised. Colonic irrigations are not so popular

since we have learned that they may result in a true colitis where only a questionable one existed before. But how frequently do we sit down and talk over with the patient his fears and hopes, his joys and sorrows? The answer is discouraging.

ULCERATIVE COLITIS

We now come to a disease, nonspecific ulcerative colitis, which until recently has always been considered bacterial in origin. Superficial comparisons of autopsy material from this disease with that from bacillary or amebic dysentery would immediately suggest a bacterial or protozoal etiology. I shall not go in detail into the evidence supporting either of the two leading schools of thought, one believing that the disease is an attenuated dysentery and the other that it is due to a specific diplococcus. Each group can find bacteriological and experimental evidence to support its stand. For therapeutic results you can take your choice for each group reports good results in seventy-five per cent of the cases, one with polyvalent anti-dysenteric serum¹⁴ and the other with antidiplococcus serum.¹⁵ Others have obtained the same results with transfusions¹⁶ or mercurochrome intravenously.¹⁷

Have gastroenterologists always been satisfied that the disease was bacterial in origin? By no means, for other etiological agents have been suggested such as vitamin deficiency or disturbance in calcium metabolism. In 1923 Logan⁸ came to the conclusion that bacteria were secondary invaders of the walls of the colon. He suggested that changes in the digestive juices of the upper gastrointestinal tract or in the endocrine secretions were responsible for the local lowering of tissue resistance. He said, "It thus seems probable that a general metabolic disturbance is responsible for the trouble." In 1925 Thomas R. Brown¹¹ wrote "Is it not possible that the cause of the disease is to be found not in the presence of a definite and specific infective agent but rather in the absence of some protective substance or mechanism of something which normally inhibits the bacterial invasion of the intestinal wall perhaps due to metabolic error, or endocrine disturbances or lack of specific bacteriophage or absence of some normal bactericidal substance in the intestinal mucosa."

To the late Dr Cecil D. Murray¹² belongs the credit for demonstrating that this disease may be psychogenic in origin. Interestingly enough this was discovered only because ulcerative colitis was included in a group of disorders in which it was thought desirable to investigate psychogenic factors. Murray writes¹³ "The fact that the Constitution Clinic in the Department of Medicine was undertaking a special investigation of the psychological panel

in certain disorders is the only reason why this and other patients were referred to us for psychotherapy. Although this patient was described as 'nervous', she did not complain of mental symptoms and would not have fallen into the group ordinarily referred to the psychiatric clinic." In 1930, Sullivan and Chandler¹⁴ added five cases to Murray's twelve and gave a follow-up of one of Murray's cases. In 1935, Sullivan¹⁵ added nine more cases and included follow-up studies of the entire group some as long as four and a half years. Jones¹⁶ and Daniels¹⁷ have added other cases.

These studies show a striking unanimity in the underlying psychogenic factors. Primarily a disease of young adult life, it affects those with definite infantile elements in their emotional make-up who are unable to adjust themselves to the sexual and financial responsibilities of adult life. Nearly always there is a well marked time relationship between emotional crises and the onset of the disease or its recurrences. The patients have many personality traits in common. Psychotherapy is astonishingly successful.

We now have partial answers to some of the problems which have frequently arisen in this disease. Why should it take its toll of youth in its best period, "Frequently the recent bride or the vigorous youth in his college years, or a young husband and provider"?¹⁸ And we hope that an end has been put to such therapeutic nihilism as this¹⁹ "The writer has gradually reached the conviction that in the individual case the patient's course is somehow predetermined from the start regardless of therapy. This idea has come from the experience that some patients get well promptly under any form of therapy, whereas others seem totally refractory to all measures."

SUGGESTIONS FOR FUTURE INVESTIGATIONS

In reading the literature on ulcerative colitis I have been struck by the brevity with which the social and psychological background of the patients has been treated. Whole pages of possible emotional conflicts have been indicated by such phrases as, "a widow of 23" or "an unmarried Jewish girl of 29." The study of the patient has ended with such a phrase though the study of the disease would fill volumes. In only one case was enough of the patient included to enable us to say that psychogenic factors may have played a rôle in this instance. Trousean²⁰ reports a case, "The patient stated that two years ago she was living in Champagne when she was obliged by the pressure of poverty to seek a home elsewhere. Accompanied by her husband and one child, the sole survivor of six she came to Paris to seek a subsistence. In this attempt she failed and in place of obtaining the hoped for relief she got involved in still deeper

misery Her husband fell ill, she, he, and the child had nothing to eat save the ration of bread allowed by public charity" The diarrhea was of two years' duration, therapy was unavailing and the patient died Autopsy showed nothing but superficial ulcerations of the colon

The problem, as I see it, is this Here is a disease which in some instances, at least, is emotional in origin Are we going to continue to dismiss the patient and his problems with a phrase, the result of a few superficial questions? Are we going to neglect emotions in ulcerative colitis as we have in mucous colitis? Is it scientific to study only bacterial flora and immune reactions and mere nonsense to probe into the patient's psyche?

In order to demonstrate what I believe the true investigation of these psychosomatic disorders involves, I find it convenient to borrow illustrations from Crookshank²⁹ and Alexander³⁰ Crookshank has written

"It always seems to me odd in the extreme that doctors, who when students, suffered from frequency of micturition before a viva voce examination, or who when in France, had actual experience of the bowel looseness that occurred before action, should persistently refuse to seek a psychical correlative—not to say an etiological factor—when confronted with a case of functional enuresis or mucous colitis I often wonder that some hard-boiled and orthodox clinician does not describe emotional weeping as a 'new disease', calling it paroxysmal lachrymation, and suggesting treatment by belladonna, astringent local applications, avoidance of sexual excess, tea, tobacco and alcohol, and a salt-free diet with restriction of fluid intake, proceeding, in the event of failure, to early removal of the tear-glands This sounds of course, ludicrous But a good deal of contemporary medicine and surgery seems to me to be on much the same level"

Here, then, is the so-called "scientific" method of studying paroxysmal lachrymation, with chemical estimations of the salt content of the tears, and a correlation of this with the blood chloride level Alexander³⁰ has supplied us with a description of the psychological method of studying such a disorder in the following quotation

"It can easily be shown, however, that even the most common psychomotor processes cannot be satisfactorily described without the precise knowledge of psychic factors As an example, the process of weeping or laughing may be considered, both of which are based on complicated psychomotor reflexes A statement that sad ideas are able to influence the function of

the lacrimal glands is a vague generality the scientific uselessness of which becomes clear from the following imaginary experiment The problem is to establish those conditions under which the physiologic processes of weeping are provoked in different individuals Let it be assumed that to solve this problem a hundred individuals are exposed to a moving picture It will then be observed that by a certain touching scene a certain percentage of the hundred are unable to control their tears and react with the unsuccessful suppression of sobbing, whereas another group are much less touched and a third group remain entirely cold and observe critically the plot without any emotional participation in it It would be, however, entirely false to jump from these differences of reactions to the conclusion that the persons who remained cold are less sentimental in general, because a second experiment will prove that, confronted with another scene on the screen, a great percentage of those who remained undisturbed by the first scene will now react with intensive sobbing and crying If this kind of observation in exposing the experimental individuals to different scenes is patiently followed up, it may be possible to distinguish certain specific situations to which certain groups of individuals react with weeping and the specific sensitiveness of certain individuals to certain situations might even be considered as a characteristic feature of them Experimentation may lead one thus far in this complicated field, but, if one wants to have a deeper insight into the intricate process of weeping, it will be necessary to investigate each individual separately Such an individual psychological study necessarily leads to very complex psychological causal chains In order to establish the specific sensitiveness of the experimental subjects to certain scenes, one must know their past life history, the whole development of their personality, because one will be able to understand the conditions under which an individual cries only from the experiences of his early life The significance is now apparent of my former statement that the psychophysiological process of weeping cannot be described by a general statement that certain sad ideas or impressions are able to influence the function of the lacrimal glands If scientific demands regarding psychomotor processes are to be as strict as those accepted for somatic processes, the psychological side of a psychomotor reaction has to be investigated with the same precision as is usual in studying organic processes"

If, in the foregoing illustrations, we substitute the colon for the tear glands, and diarrhea for weeping we have an idea of how our problem should be attacked. Not for a moment do I believe that psychological studies will provide the answers to all our questions. There is much to be done on the somatic side, the mechanisms involved in the hyperperistalsis, the hypersecretion of mucus and the production of ulceration have still to be solved. There is plenty of scope for those investigators who will continue the work so ably begun by Cannon, Alvarez and Cushing. However, in the care of our patients there is an immediate need for physicians interested in the psycho investigation and treatment of such psychosomatic disorders. In this group are included not only diarrheal diseases but also essential hypertension, Graves' syndrome, gastric and duodenal ulcer and cardiospasm.²¹

CONCLUSION

Material from the literature has been presented to illustrate the close relationship between emotion and diarrhea. An attempt has been made to show that diarrheal disease usually considered organic may be emotional in origin. A plea has been made for the substitution of thorough personality studies of these patients in place of our present "skillful neglect." Perhaps I may be allowed in closing, to express two hopes.

First, that the present generation of physicians may keep in mind what was written by Hawthorne²² in the "Scarlet Letter": "A bodily disease which we often think of as a thing apart and separate, may after all be but a symptom of an illness in the spiritual part of our nature."

Secondly, that the coming generation of physicians will have been so taught in their medical curriculum that they will feel as Mohr²³ does that, "There is no such thing as a purely psychic illness or a purely physical one but only a living event taking place in a living organism which is itself alive only by virtue of the fact

that in it psychic and somatic are united in a unity."

THE PREVENTION OF DECAY OF TEETH

Science reports that decay of the teeth with attendant toothaches may be prevented if a method developed by Dr. E. P. Brady of the Washington University Dental School is put into successful practice. A dental examination can determine by a chemical test which of the teeth in one's mouth are liable to decay. Silver nitrate, a common drug used generally for germ killing purposes betrays the presence on the tooth enamel of certain faults of formation. It is in these faulty areas that decay is likely to start because there the acids in the

month and acid producing bacteria can penetrate through the enamel to the sensitive dentine beneath. The decay can be prevented by the use of silver nitrate. After it has started its progress can be stopped by use of another chemical called trichloroacetic acid. Dr. Brady said. This substance acts to coagulate the organic material in the tooth and block any further penetration by the acids of decay into the interior of the tooth. Nature has her own way of doing just this under favorable conditions. When decay starts a defense may be made in the form of a barrier of calcium deposit across the path of the penetrating acids.—*Science*

NEW HAMPSHIRE MEDICAL SOCIETY

TREATMENT OF BURNS*

BY GROVER C PENBERTHY, M D †

A REVIEW of the literature which refers to the treatment of burns indicates that the greatest amount of constructive thinking and work along lines of practical therapeutics has been done in the last two decades. It is also apparent that in spite of the advances made in the treatment of burns the general mortality remains high. No definite explanation can be given for this as there are many factors which contribute to the mortality. The care of the burn lesion still remains a serious surgical procedure. The ability of the human body to withstand the severe burn appears to be an individual problem, with the very young and the very old reacting poorly.

Statistics¹ show that about 45 per cent of the lethal burns occurring annually in the United States are in children under six years of age and in this group the outcome is often out of proportion to the severity and extent of the apparent damage done. At the Children's Hospital in Detroit, where 547 cases have been studied over the past twelve years, the greatest number fell in the age group one to three years.

The management of a burn case develops practical and theoretical considerations. Many questions have been raised and it is obvious that there are problems for further research before we can agree on any standard form of treatment especially in the complicated cases.² There are advocates of the continuous saline bath³, the paraffin wax method⁴, the use of gentian violet⁵, which has a decided advantage in minimizing infection, and many others.

In discussing the subject of burns it appears that up to the time that Davidson⁶ brought out the use of tannic acid many of the clinics and physicians had adopted methods of their own and were satisfied with the results obtained. The oils, ointments, and other remedies were used with gauze dressings applied, which usually adhered to the burn area and caused pain and bleeding when removed. The extensive burn was usually given a bad prognosis, and the less severe case became infected, running a protracted course and developed deformities due to contracture.

The work of the late Doctor Edward C Davidson is a contribution to medical science and it is with pride that we in Michigan refer to the results of his laboratory and clinical research.

*From the Surgical Service of the Children's Hospital of Detroit, Michigan.

Read at the Annual Meeting of the New Hampshire Medical Society at Manchester May 8 1935.

†Penberthy Grover C—Associate Professor of Surgery, Medical School of Wayne University. For record and address of author see "This Week's Issue" page 323.

It was my good fortune to have the opportunity of working with him at the Children's Hospital⁷, where the technic, which will be shown in the movie film, was perfected. His work has also had its effect in stimulating others to perfect methods of technic in the treatment of burns, which will assist in reducing the mortality. The advantages of the tannic acid form of treatment and the results obtained by its use have been emphasized in a number of published reports^{8 9 10 11 12}.

In referring to the use of tannic acid, Wells makes the following statement, "The introduction of tannic acid by Davidson in 1925 has revolutionized and apparently for the first time in history standardized the treatment of diffuse burns."

The early symptoms following a burn are primarily those of shock with a profound disturbance of the circulatory and heat regulating mechanism, and, in all probability, equally serious interference with many other normal functions of the body. The larger the area involved, the greater are the number of nerve endings and neurons irritated, resulting in a greater degree of shock. It has been shown by the experimental work of Davidson that a burn causes a marked depression in blood chlorides^{13 14} that the toxemia accompanying a burn is due to a toxic agent which originates at the site of the burn, that the absorption of this agent is responsible for the constitutional reaction, that the local destruction of tissue gives rise to a proteid substance with the subsequent formation of a proteose, and, finally, that the latter is the toxic element in burns.

Vogt¹⁵ and later Vaccarezza¹⁶ observed that when parabiosis was established between two animals and one was burned the other showed evidence of toxemia. It was further demonstrated that toxic symptoms did not develop in the unburned animal when it was separated from the burned animal within twelve hours, but that both animals finally died of toxemia when left united.

Pfeiffer¹⁷ isolated toxic cleavage products of protein decomposition from burned skin. Robertson and Boyd¹⁸ demonstrated the toxicity of the products of protein autolysis of burned tissue. They further showed that the toxin circulated in the blood stream and upon this was based their clinical work of exsanguination transfusion.

The clinical⁶ and experimental facts suggest that the rational manner of combating the toxemia would be some form of local treatment.

which would prevent absorption from the site of the burn. This has been attempted in a number of ways. Débridement has deserved a certain amount of popularity but its application is limited by the severity of the procedure.

Tannic acid is a nonnitrogenous amorphous powder readily soluble in water, glycerine and alcohol but insoluble in ether and chloroform. It precipitates proteins alkaloids, some glucosides and the salts of heavy metals. It forms a more or less stable compound with the protein constituents of the body fluids and cells thereby preventing the loss of body fluid at the site of the burn. The astringent effect appears to be limited to the superficial layers of tissue. The precipitated proteins on the surfaces treated, prevent and minimize the absorption of the autolytic products of protein decomposition. In addition, the precipitated proteins provide a protective coating and a mechanical action against sensory and inflammatory irritation. It is used with the idea of precipitating the toxic elements in the burned tissue thereby preventing their absorption. Tannic acid is used as a five per cent aqueous solution freshly prepared and applied to the burned area by a DeVilbiss spray. A burn when exposed to the air is very painful and the earlier it is covered with tannic acid the degree of pain and shock will be greatly diminished.

The treatment of burns is best carried out in the hospital.¹⁰ Patients admitted in shock can be put in a light tent or the heat may be applied in another way by an electrically heated blanket or many hot water bottles placed about the patient. Morphine or codeine should be given freely for the pain. This allows the patient to rest the first night and having had this rest he is better fitted to take the forcing of fluids the following day. One of the most essential features of the management of all burn cases is that of keeping up the fluid balance in the body.⁶ For the more severe burns saline should be given by hypodermocentesis or intravenously with glucose as the needs indicate, in addition blood transfusion and thus repeated as often as indicated.

The local treatment of burns depends to a large extent upon the experience of the surgical staff. The general rule, however, is to wash the acid and alkali burns with water before applying a neutralizing agent and to remove all devitalized superficial tissue, as well as opening and draining the blisters with as little trauma as possible. The patient is then placed in a light tent upon a sterile sheet and the tannic acid spray started by the nurse.

The burned area is sprayed every fifteen minutes for the first four to six hours at which time there is usually a brownish black firm leathery coagulum formed. The time required for this spraying depends upon the depth of

the burn and the reaction of the tissues to the tannic acid. It is our practice to use the tannic acid jelly for burns of the face. The first application of the tannic acid gives the patient relief from pain and as the precipitate increases it becomes black and hard giving a firm protection which is a distinct advantage. As the epithelium regenerates, the coagulum or tannic leathery coat curls up at the edges.

It has been found in our use of the tannic acid in the treatment of burns in children that the mortality has been reduced from 86 per cent to less than 10 per cent. These figures compare very favorably with those reported from other clinics.^{10 11}

The treatment of any burn case becomes an individual problem, but to insure the best end result requires strict adherence to the accepted principles of treatment as proposed by Davidson and others. This treatment in the majority of cases should reduce the mortality and assist in preventing the unfortunate occurrence of many complications.⁹ Prompt application of local treatment,⁹ proper supportive measures follow up care and attention together with early skin grafting, along with the correction of deformities, offers a reasonable hope for success.

SUMMARY

- (a) Burns have carried a high mortality and are best treated in the hospital. The standardization in the treatment of diffuse burns, by the use of tannic acid, has materially reduced the mortality and thus contribution to the subject by Doctor Davidson has resulted in the saving of many lives.
- (b) Administrations of a sedative upon admission.
- (c) Washing the chemical burns with water is essential before applying the neutralizing agent.
- (d) Proper first aid followed by early hospitalization and aseptically cleansing the burned area is important.
- (e) The tannic acid method of treatment, combined with the light tent, is effective and helps to simplify the treatment of a condition that can tax the patient, time and resources of the attending physician to the utmost.
- (f) The use of tannic acid lessens the loss of body fluids and the coagulum acts as a protection against infection.
- (g) The forcing of fluids and giving saline solution, either subcutaneously or intravenously and blood transfusion are necessary to carry the patient through the acute period of toxemia.

- (h) Early skin grafting of the third degree lesions will minimize the amount of scarring and deformity. It will also lessen the period of morbidity and disability.
- (i) The severe burn case often requires subsequent plastic surgery to improve the function of an extremity or better the cosmetic result.

DISCUSSION

PRESIDENT LORD. This paper of Dr Penberthy's on the Treatment of Burns with Tannic Acid will be discussed by Dr Walter H Lacey of Keene.

DR. WALTER H LACEY. *Mr President and Gentlemen of the New Hampshire Medical Society—* This paper constitutes a direct appeal simply put, to give our burn cases better care, especially the severe cases. The earlier you get the burns cleared up, the sooner you can graft, and the sooner you graft, the less the trouble will be, and this shows us the way.

It is interesting to note what some of the larger clinics in New England are using at the present time. The Children's Hospital in Boston is using tannic acid spray and contemplating using the tannic acid bath.

At the Massachusetts General Hospital the tannic acid bath at 100° F is being used and it is felt that this is an advance in treatment.

At the Johns Hopkins and New Haven Hospitals, gentian violet is being used and it is felt that it is more analgesic and keeps the lesions cleaner.

At the Presbyterian Hospital in New York, tannic acid compresses are being used.

All of these clinics, like ourselves, are bothered by the first aid treatment of greasy dressings applied outside which makes the initial clean up at the hospital a little harder to do.

If we get the public and the nursing profession, as well as the doctors, to appreciate the value of these drying and tanning dressings, as outlined with such justifiable enthusiasm as Dr Penberthy has, our burn cases will suffer less and get well more quickly. I thank you.

PRESIDENT LORD. I will call upon Dr James W Jameson of Concord for a further discussion of this paper.

DR. JAMES W JAMESON. I think we owe a debt of gratitude to Dr Penberthy for his excellent paper and for his very instructive illustrations of the tannic acid treatment for burns.

Since the work of Dr Davidson on the treatment of burns with tannic acid, a great deal more thought has been given to this condition than ever before, with the result that the mortality in burns has been lowered and probably will be decreased further in the future.

The older forms of treatment with carron oil, various powders and ointments and things of that kind, without any regard to asepsis, employed just as a first aid and then continued, have made the mortality of burns very high, due especially to the factors which attend this serious condition.

The dressings which have been used in the past have been painful. They have required frequent changes, they have prolonged the period of disability and not only caused loss of time, but very definite economic loss.

Dr Penberthy has covered these various factors which are the important ones in burns, first of all, shock, next the loss of body fluids, which someone has estimated that in the course of the first twenty-four hours, a burn covering one sixth of the body will mean a loss of at least seventy per cent of the body fluid, thirdly, the absorption of the toxic products of the burn, and fourthly, the infection.

I feel that any form of treatment which will cut down the mortality, and which is simple in its use, is the one which should be used.

Gentian violet has been spoken of, and it has appealed to me very strongly for the simple reason that it has a bactericidal action, which, of course, tannic acid does not have.

The treatment of the serious burns, that is, the second and third degree burns and those are the ones we are considering, is practically the same, in any method which you use. That is, the shock must be combated, the loss of fluids taken care of by hypodermoclysis, and other methods of increasing the fluid intake and the toxic products removed but then—as contrasting between tannic acid and gentian violet, you have one which produces a coagulum without any antiseptic property, and another which produces coagulum with an antiseptic property.

I have had no cases in which I have used gentian violet, but I have felt that it was a very satisfactory form of treatment theoretically. I should like to ask Dr Penberthy about that and whether they have compared the treatment of gentian violet and the treatment of tannic acid.

The one difficulty which I have had in using tannic acid is in those cases where infection occurs somewhere in the middle of the tanned area, and fluctuation or tenderness cannot be found early,

then after a period in which the patient has been running an irregular temperature and has shown signs of sepsis a definite abscess is usually found. This is probably due to improper preparation of the burned area before it is treated and occurs usually in the extensive deep burns.

I think that Dr Penberthy has presented a fine paper to us and it should be of great interest not only to the medical profession but to the lay public, because as has been said the first aid treatment in these cases has oftentimes been the cause of a good deal of difficulty later on.

PRESIDENT LORD This paper is now open for general discussion.

DR. THOMAS W. LUCE I simply wanted to say that I own a book, which I think is a very valuable publication because it was printed and published in Portsmouth in 1803. It was written by Dr Pitman of London, who put out this edition in America. His purpose was to have it go into the homes of people for them to get suggestions and to know how to treat diseases. In this book there is a chapter on burns.

Apparently in that day the preponderance of burns was in old ladies, who sat beside the fire. So be devout quite a bit of that chapter in telling them that they should wear woolen skirts and not crinoline and that they shouldn't open the door and scream but that they should lie down and roll over. Then he goes on to discuss the treatment of burns. He starts out by saying "Never under any circumstances put grease on the burn" because it does no good but does harm because it prevents the action of other remedies that are beneficial. Now that gentlemen was in 1803 Dr Jamieson has spoken about the old methods but we find this pretty reasonable.

Then continuing in the book, he says that in every household there should be a bottle of brine in which there always were some sliced potatoes, so that the burn could be immediately covered with that solution.

The trouble I have with burns is that practically every burn I have to treat has been treated before I got it with lard and all that sort of thing. I think if that old book could be reprinted at least that chapter on burns, and given to every family it would be very helpful today.

PRESIDENT LORD Is there further discussion on this paper of Dr Penberthy?

DR. HARRIS E. MOCK Mr President and Gentlemen—I have heard Dr Penberthy give this paper a number of times when he has talked on this subject of burns and I am impressed with the kindness and the sincerity with which he always refers to the work of Dr Davidson. We owe a great deal to Dr Davidson for doing the early research work in tannic acid treatment of burns. But I think the country over, and the profession owes a great deal if not the most, to Dr Penberthy for popularizing the treatment of burns with tannic acid. He is so modest about it himself that you would never know this from him but I don't believe there is any man in the country who has done more toward bringing the mortality rate down and relieving suffering from burns than has Dr Penberthy.

I want to add to the list of hospitals that one of the speakers gave St. Luke's Hospital in Chicago. Tannic acid is used there practically altogether in the treatment of burns.

I would like to emphasize one point, viz., the tent, left at an even temperature by means of an electric light bulb and allowing the patient to lie under this tent completely naked. This adds materially to the ease of caring for these cases.

And one point about the infection. Dr Penberthy simply mentioned one case where they didn't do it over with the tannic acid because it was infected. Often when you get these cases after two or three days at home and then brought into the hospital, they are infected and I would like to have Dr Penberthy emphasize just what they do about putting tannic acid immediately upon such cases.

DR. ROGERS Dr Penberthy mentioned that eighty per cent of his burns were avoidable also that about ninety-nine per cent were in the nonpaying group. You know the condition of the minds of people surrounding a child who has convulsions. Sometimes the child is put into too hot water by the parent.

I feel that as we have contacts with our patients and as we have frequent opportunities to address public gatherings we should speak on these dangers.

DR. ARNOLD S. MANGRUM Tannic acid treatment is an old fashioned treatment and we do not know it. When I was a young boy I recall burns being treated in this manner. One would gather leaves from the English walnut, or if these could not be obtained leaves from the oak tree. The leaves of the walnut are long wide and thin somewhat resembling those of the rubber plant. The leaves are boiled as one boils spinach cooled and spread over the burns. Both varieties contain a large percentage of tannic acid.

Tannic acid is also used in dyeing rugs if a good brown color is desired the wool or yarn being boiled in the solution obtained from the leaves. The concoction derived from the leaves is also used as a hair dye, which gives a nice brown tint to the hair acts as a tonic to the scalp and the roots. This vegetable dye is much better than the acid ones used in cosmetics in many countries.

Even now I have found in my practice many people using old fashioned remedies. I am much interested to find out their ingredients and have come to the conclusion that many of them contain the desired remedy and therefore, am never angry to find a patient using some old-fashioned remedy.

DR. PHILIP H. GREELY Mr President and Fellows—I would like to add what I believe is a valuable prophylactic hint for the family or anyone of us who happens to come in contact with extremely hot water.

If cold water is dashed on to the injury at once the destructive cooking is checked immediately whereas if the assistant tries to remove clothing valuable time is lost and a bad injury results. As a personal experience helps to impress a valuable suggestion I will say that I have often heard my mother explain that she gave me this treatment when I sat down in a pail of near boiling water and saved me from serious results with a convenient pump and hasty action.

I believe if this could be broadcast into every home many a child might be saved serious injury.

PRESIDENT LORD Time passes very rapidly we can't seem to help it. I think that the evidences of interest in Dr Penberthy's paper have been obvious this morning and I will ask him to say a few words in closing.

DR. GROVER C. PENBERTHY I wish to thank the discussants for their kind remarks. The subject of burns is of interest to all of us and naturally the general practitioner must see more burns than we do in the clinics.

It is very interesting to hear the experiences of the other men. We all have our problems and it is very apparent that we are all thinking along the same lines. It speaks for good medicine. It means

education of the public I think Dr Rogers mentioned the education of the public in the prevention of burns, which is very important. Since the laymen have an understanding of the importance of these matters, it is only a question of time when, perhaps, we can cut the mortality to a figure even lower than it is at present.

The matter that Dr Jameson referred to regarding infection in the middle of the coagulum, I would say is apparent many times. Where the infection manifests itself, that coagulum, of course, should be cut, if not removed, in order to allow surgical drainage. The presence of pus and the absorption constitute a factor which contributes to the exhaustion of the patient. Exhaustion hasn't been mentioned in this paper, but I am sure you all realize that as the effect of the burn goes on, with the loss of body fluids, the patient naturally becomes exhausted. That is one of the reasons for frequent blood transfusions. The removal of the coagulum as shown in the movie is the practice that we carry out. Where there is infection we must remove it.

The book that Dr Luce referred to is very interesting, and when the mention of the brine bath was brought out in the book, it brought to my mind the work of Dr Blair. He is a strong advocate of the brine bath, and for the old, protracted case, that seems to resist all treatment, the brine bath should always be considered, that is, in the late stages of the burn, where the epithelialization is slow. Where the wound is infected, it is our practice to place the patient in the brine bath.

I wish to take this opportunity to thank Dr Mock for his remarks. We all owe a great deal to Dr Davidson, and, as has been mentioned, he stimulated a great many to think of the treatment of burns. It is unfortunate that he should have been taken so early in life.

The time period for the application of tannic acid is, I think, a personal problem. We have cleaned

up wounds coming in twenty four hours after the accident and applied the tannic acid, and we have been successful. I think the burn that comes in, we will say, forty eight hours old, and which is infected, should not have tannic acid, it would be a great mistake to apply the tannic acid to this type of burn. I think in that particular type of case, Dr Aldrich's work in the use of gentian violet is the treatment of choice. He told me last night that he had a new dye which he thinks is superior to gentian violet. I would say that the infected case which comes in late should not have tannic acid because there is infection present and pus will collect under the coagulum adding to the exhaustion of the patient.

The question of the application of home remedies as mentioned by Dr Mangurian, is also very interesting, and, if we look back on the ideas of some of the people who have gathered a little information here and there, we find that they have used practical therapeutic measures in combating some of the problems.

In an editorial in the *Journal of the American Medical Association* in the November 17, 1934 issue in the correspondence column, a physician in Pittsburgh referred to a paper that was published in the *Medical Review* in Pittsburgh in 1890. He mentioned the fact that tannic acid was used as a 5 per cent solution by soaking the sponge in the solution and squeezing the solution onto the burned area.

If you go into the history of burns and go back into the work of the Chinese hundreds of years ago where they used tea, you will find that they were thinking of the same problem and trying to arrive at some method of treatment which would lower the mortality. That is our responsibility as physicians, to lower the mortality of any condition we may treat.

I wish to thank the Society for giving me this opportunity to present this interesting subject.

THE HEART IN RHEUMATIC FEVER*

BY CLIFFORD L. DERICK, M D †

BEFORE discussing any phase or manifestation of a disease, it would seem wise to pause and consider the disease itself in its entirety. The question may well be raised as to what Rheumatic Fever is. A definition in other than descriptive terms is impossible at the present time. Dr Homer F. Swift, who has spent the past fifteen years in an exhaustive study of this disease, has defined Rheumatic Fever as "A disease of undetermined etiology characterized by fever and a toxic state, and by the presence in certain organs of the body of small disseminated focal lesions of a proliferative type. In acute stages there is also an exudation in and about the joints, and sometimes in the pleurae and pericardium. A further characteristic is the tendency for the febrile and arthritic symptoms to disappear when the patient is given large doses of compounds of salicylic or phenyl cinchoninic acids."

Let us study this definition more in detail.

*Read at the Annual Meeting of the Grafton County Medical Society at Hanover N. H. October 12, 1935 and at the Springfield (Mass.) Academy of Medicine September 10, 1935.

†Derick, Clifford L.—Senior Associate in Medicine Peter Bent Brigham Hospital. For record and address of author see This Week's Issue page 328.

First, it is a disease of undetermined etiology characterized by fever and a toxic state. The causative agent of rheumatic fever is still unproved though most workers in this field consider it to be some member of the streptococcus family. Although in its more acute stages it runs a febrile course with leucocytosis, sweating, rapid pulse rate and other manifestations commonly associated with an infection, there most probably is not an invasion of the blood stream by the streptococcus. Existing evidence is more in favor of there being a general tissue hypersensitiveness to the streptococcus similar to what is found with the tubercle bacillus in tuberculosis. Following a tonsillitis or other infection, usually of the upper respiratory tract, due to the streptococcus, toxic products of this organism are carried by the blood stream and cause lesions wherever they may lodge. Support for this theory is obtained by the type and severity of response shown by rheumatic individuals when extremely small amounts of killed streptococci or their products are injected either into the tissues or intravenously. A virus has been claimed as the etiological agent

by some workers but as yet there is little evidence to substantiate this conception.

Secondly, the definition states "the presence in certain organs of the body of small disseminated focal lesions of a proliferative type." These focal lesions are considered characteristic of rheumatic fever in the same sense as the tubercle is for tuberculosis and the gumma for syphilis. Their nature and composition will be discussed later. These lesions are always in and around blood vessels and are most commonly found in all parts of the heart, the synovia of joints and the subcutaneous tissues where they manifest themselves as subcutaneous nodules. They are found also in the lungs, kidneys, tonsils, serous membranes, and fatty tissue about various abdominal organs. It is most probably true that they occur in any part of the body where there are blood vessels. It is for this reason that nowadays rheumatic fever is considered a general disease and not simply an arthritis with fever. This conception really dates back to 1888 when it was recognized how frequently the heart was involved and left permanently damaged. In other words carditis is as much a part of the disease rheumatic fever as is arthritis. In fact, one may go farther and state that in children, in which age group rheumatic fever is most common, carditis is more frequent than is arthritis. At this age involvement of only one or no joint may be observed. The converse holds true in adults where arthritis is usually outspoken and carditis occurs with less regularity.

Thirdly, in the acute stages there is also an exudation in and about the joints, and sometimes in the pleurae and pericardium. That this statement holds true for the involved joints has been recognized always and needs no further comment. Until recently, the presence of fever and free fluid in the pleural spaces was considered to be tuberculous in origin. It is now known, however, that in children especially this effusion frequently is part of a rheumatic fever infection. This is proved by the failure to demonstrate tubercle bacilli in the fluid, the failure to have tuberculosis manifest itself elsewhere in the body and more especially, by having other evidences of rheumatic fever such as arthritis or carditis appear during the course of the illness.

Fourthly, the tendency for the febrile and arthritic symptoms to disappear when the patient is given large doses of compounds of salicylic or phenyl methanonic acids. The action of these drugs upon the exudative manifestations of rheumatic fever is almost specific. So much so that many recommend the administration of these drugs as a diagnostic aid. Neither fever nor effusion when due to any other cause, such as tuberculous infection, responds to any comparable degree. The therapeutic use of these drugs will be discussed later.

Thus rheumatic fever as a general disease with protean manifestations is easily visualized. It may have struck some of you as peculiar that up to now I have not used the term acute rheumatic fever. My reason for this is that in most instances rheumatic fever does not run an acute course and terminate with no ill-effects. It is noteworthy that in 1928 the American Heart Association in its publication entitled "Criteria for the Classification and Diagnosis of Heart Disease" omitted the use of the adjective acute. The disease may run any one of three different courses—

- (a) Monocyclic
- (h) Polycyclic
- (c) Continuous

(a) *Monocyclic*—About twenty five per cent of all cases have a monocyclic course, that is, after an active attack, evidence of the disease disappears and so far as one can judge the patient is cured. This is found to occur much more frequently in adults than in children and there is less likelihood of permanent damage to the heart in this group of cases.

Slide I—This slide shows the story of an attack of rheumatic fever in two men, one thirty three and the other forty seven years of age. In each instance it was the first attack.

It is worth pointing out what observations on these patients are recorded at the Hospital of the Rockefeller Institute in New York City. An attempt is made to fill in the story of joint involvement before admission to the hospital. During the hospital stay observations on temperature, pulse and respiratory rates, white blood cells, conduction time of the heart, condition of joints, administration of drugs, weight, and fluid intake and output are recorded daily or at frequent intervals as shown in these charts.

In the case of this first man, the temperature quickly returned to normal and his joints cleared up. No antirheumatic drugs were used. This patient was kept in the hospital for forty days without further evidence of activity and he has remained free from any recurrence since.

The second patient can hardly be classed as having run a monocyclic course as he had a recurrence of joint activity with a slight elevation of temperature as shown in the chart, in spite of the continued use of salicylates.

Slide II (b) Polycyclic—It is much more common—over fifty per cent of all cases—to have the disease run a polycyclic course. That is to have all or most evidences of activity clear and then to have the patient go through another attack very similar in every way to the first. These recurring cycles occur with considerable regularity about every twenty to thirty days in the different patients. It is quite usual to find each succeeding attack

(b) Rhythm Disturbances of cardiac rhythm are not uncommonly met with in rheumatic fever and when present practically always indicate that the heart is involved. The less serious forms of disturbed rhythm are absence of sinus arrhythmia, which is normally found in children, and the presence of extrasystoles. The more serious arrhythmias are heart block, auricular flutter and auricular fibrillation. These latter always indicate serious myocardial damage frequently with an accompanying pericarditis. The nature of most of these irregularities can be detected at the bedside. This, however, is not always true, for at times the evidence of extrasystoles or some degree of heart block is so similar that differentiation can be made out only by means of an electrocardiogram. They will be discussed later under Laboratory Aids.

(c) Venous engorgement and peripheral edema. When other causes of obstruction to the return flow of blood can be ruled out, the presence of engorgement of the neck veins or edema of the lower extremities signifies a very much weakened and inefficient heart. The presence of these signs always means a much damaged myocardium which frequently is further overloaded by the presence of incompetent valves.

(d) Size of heart. Signs of slight cardiac enlargement are frequently present in the acute stages of rheumatic fever and may have no great significance. On the other hand moderate to marked enlargement does have considerable significance and is due either to an accumulation of fluid in the pericardial sac as part of a pericarditis or to hypertrophy and dilatation of the heart itself which means that there is a severely damaged myocardium and probably endocardium as well.

(e) Heart sounds. Useful information can be obtained by listening repeatedly to the heart in rheumatic fever patients. Things to be listened for are the character and intensity of the sounds, whether there is a reduplication or gallop rhythm, the presence or absence of murmurs and the presence or absence of a friction rub.

Heart sounds are diminished in intensity in the presence of pericardial effusion but more frequently the diminution is due to loss of tone and weakness of the heart muscle when this has been widely involved by the rheumatic process.

Reduplication of sounds or gallop rhythm is observed frequently to come and go during an attack of rheumatic fever with carditis but its cause is unknown unless it means that the muscle of one side of the heart is more damaged and weaker than that of the other side.

The continued presence of murmurs is of definite significance though they of themselves are not given at present so much weight as in previous years. This is due to the fact that

murmurs which are easily heard when the heart is rapid may disappear entirely when the rate is slowed and probably when a slight dilatation of one or another chamber of the heart has disappeared. Dr. Henry Christian teaches us not to place too much value as to diagnosis and prognosis of the amount of damage to a valve on any murmur heard during the acute stages of the disease when fever is present. On the other hand murmurs, especially diastolic in time, which are present at a later stage have very definite significance. The valves of the left side of the heart, namely mitral and aortic, are much the most frequently involved.

The presence of a friction rub over the precordium is the most conclusive evidence that the pericardium has been involved. Since these rubs may be of short duration it is important that auscultation be repeated daily, especially in the presence of precordial pain or hyperesthesia which may be the first symptom of pericarditis.

(3) Laboratory evidences of cardiac involvement

The outstanding laboratory aid in determining whether the heart is involved is the electrocardiograph. Its great usefulness lies in the fact that it will pick up and determine the true nature of lesser degrees of heart block which can be made out in no other way. Since the conduction of the cardiac impulse from auricles to ventricles is intimately associated with the heart muscle any changes observed in the conduction system must mean an involvement of the myocardium. The electrocardiograph is of no aid in determining whether the endocardium or pericardium has been invaded.

Heart block as found in rheumatic fever may be of three different degrees:

- (a) Delayed auriculoventricular conduction time
- (b) Dropped beats
- (c) Complete heart block

Slide IX This slide shows a normal electrocardiogram. Note that the time interval between the P and R waves, or auriculoventricular conduction time, is short—less than 0.2 seconds.

Slide X This slide shows delayed auriculoventricular conduction. It is quite common in rheumatic carditis, as in this instance here, to find the conduction time delayed to much longer than 0.2 seconds without failure of any of the impulses to get through to the ventricles. Since block of this degree gives no evidence that can be detected on physical examination, it must be determined by mechanical means.

Slide XI (b) Dropped beats. These occur when the A-V interval is so lengthened that some of the impulses do not get through to the ventricles. When such an impulse fails to get through, the ventricles are still for a longer

time than usual. These pauses or blocked beats can be observed clinically, but as noted previously the only sure way to differentiate them and extrasystoles is by means of an electrocardiogram.

Slide XII (c) Complete heart block. This is the most marked degree of disturbance of the conduction system when no beats get through from the auricles to the ventricles. In this case the ventricles take on their own independent rhythm. Since the rate when originated in the ventricles is a very much slower one, a change from ninety beats or over to the minute to under fifty should make one suspect complete heart block.

The cause of these alterations in the conduction system is supposed to be and probably is due to the presence of Aschoff bodies in or near the conduction bundle of His. Levy of New York has observed alterations of conduction to parallel the administration of salicylates and believes that when conduction is interfered with there is edema in and about Aschoff bodies situated near this bundle. After administration of salicylates, this edema clears similar to a disappearance of fluid in and about the joints thus leaving the conduction system to function normally.

One final question might be asked and that is as to how frequently the heart is involved in rheumatic fever. The best observations in answer to this question are those of Cohn and Swift who studied a series of cases with daily electrocardiograms. Their findings are summarized on this slide.

Slide XIII They divided their cases of rheumatic fever into three groups as follows: (1) first attack, (2) recurring attacks and (3) cardiac or continuous type.

(1) There were seventeen cases in the first group and of these fifteen showed changes in conduction time and sixteen changes in the form of the ventricular complex. Thus nearly all showed evidence of myocardial involvement. In this same group, six showed definite, ten doubtful and one no evidence of endocardial involvement while three patients developed pericarditis.

(2) In their second group with recurring attacks of rheumatic fever they had twelve cases. Of these ten showed delayed conduction and eleven some alteration in the form of the ventricular complex. All but two cases showed evidence of endocardial involvement and one had pericarditis.

(3) In their third or cardiac group, eight patients were studied. All showed alterations in the form of the ventricular complex and all had evidence of endocarditis while three had pericarditis.

When combined into a composite group one sees that ninety five per cent of all patients studied showed some evidence of myocardial involvement. Sixty five per cent showed undoubted evidence of endocardial involvement but this figure is probably too low, as many of the doubtful cases in the first group would likely develop some signs of endocarditis after a period of time. Nineteen per cent of all cases had involvement of the pericardium. Thus one may state that in practically every case of rheumatic fever the heart is involved to a greater or lesser degree. Of course that does not mean that the damage is permanent in all cases with evidence of conduction changes only. On the other hand the danger is sufficiently great to make one realize that every individual who has an attack of rheumatic fever should be suspected of having some cardiac involvement and that treatment should be so directed as to save the heart as much as possible during the acute stages of the disease.

Prognosis as regards the future of the heart in rheumatic fever is very difficult. One may say that the heart is spared frequently from permanent damage during the first attack, seldom during the second attack and probably never after further attacks. In the cardiac or continuous form, all hearts are damaged to a greater or lesser degree.

TREATMENT

The ideal treatment would be, of course, the prevention of rheumatic fever thereby removing the cause of this type of heart disease. As is true of any disease when the cause is unknown, attempts at prevention are more or less empirical. There is much evidence to show that each attack is ushered in by an acute infection usually of the upper respiratory tract. In view of this it was felt that removal of the tonsils and adenoids might prevent the disease. This hope has not been realized as shown by Kaiser working in Rochester, N. Y. After studying large groups of school children both with and without tonsillectomy he has come to the conclusion that the incidence of first attacks of rheumatic fever is slightly less among those who have had their tonsils removed at some previous time but that the removal of tonsils after an attack of rheumatic fever has little or no effect on the incidence of recurrences. Probably the sanest attitude as regards tonsillectomy is not to advise operation unless there is evidence that the tonsils are diseased as shown by recurring attacks of tonsillitis or the persistent presence of enlarged tender submaxillary lymph nodes which drain the tonsillar areas.

In a patient with rheumatic fever the most important form of treatment by far is rest both during and for a considerable time after

the attack The English school is so convinced of the value of rest to spare the heart that they treat rheumatic fever much as we treat tuberculosis in this country That is, they have sanatoria or rest homes where the patient can get rest and good nursing care for a prolonged period of time One who has worked on rheumatic fever over a period of years cannot help but realize how discouraging it is to parents, patients and the physician himself to have to recommend prolonged rest for a child who has no joint pains and who on casual examination appears perfectly normal It is only after the dangers of serious cardiac damage with their consequent permanent handicap are made clear that it is possible to get the cooperation of either parents or patients In New York City a group of special teachers are employed who conduct teaching in the homes for those who have persisting infection and are unable to attend school It is to be hoped that other communities will follow this example

The injudicious use of drugs such as aspirin, and pyramidon is to be discouraged These drugs relieve the joint symptoms, which ordinarily bring the patient to the physician, but most definitely do not cure the disease, or, in fact, have any influence in preventing or curing any involvement of the heart Evidence for this statement is that rheumatic heart disease is more prevalent now than it was before the salicylate era while the incidence of rheumatic fever itself has changed little if at all Hence, the family bottle of aspirin which can be used whenever there is an ache or a pain is a very serious problem Too often a child gets up with malaise, with or without joint pain and after an aspirin tablet feels enough better to be allowed to go to school In these cases it is only when the joints become really acute or, more frequently, when the child has other symptoms such as shortness of breath on exertion that he is brought to the physician Too late then a true picture of what has been going on is discovered Aspirin should never be given to children or young adults except with the knowledge and advice of their physicians

The treatment of the heart after it has started to fail is identical with that for failure from any other cause In addition to rest and taking as much load off as possible, one may try the use of digitalis The benefits of this drug during active phases of the disease except in the

presence of auricular fibrillation are often disappointing However a trial is warranted, since one occasionally sees spectacular slowing of the pulse rate and improvement of the circulation

The question of a change of abode to secure a more suitable climate for patients with rheumatic fever is often raised This is especially true now that it is recognized that rheumatic fever is uncommon in more mild climates such as are found in Florida, Puerto Rico, etc Recently two groups of workers, under Coburn in New York City and Jones in Boston, have sent children with rheumatic fever to some southern place for the winter months While there the children are practically free from upper respiratory infections and their rheumatism is quiescent However, in most instances the disease has become active again as soon as the children are brought home Hence if they are to remain free from active disease they must live permanently in the South This form of treatment is all right as an experiment or for the well-to-do, but is not generally applicable from an economic point of view, chiefly because it would mean moving a large group of the less well-to-do elements of society

In closing one can only hope that, with the large number of workers who are studying rheumatic fever, its cause will soon be found When this has happened its prevention and cure can be approached more sanely

RECENT DEATH

COGSWELL—SAMUEL J COGSWELL, M.D., aged sixty one, medical referee for Rockingham County, died on January 18, 1936, after a week's illness He was stricken with mumps early in the week and pneumonia set in shortly before he died

Dr Cogswell was prominent in fraternal affairs of the Knights of Pythias He was a member of the American Medical Association, the New Hampshire State Medical Society and the Rockingham County Medical Society

Dr Cogswell studied at Bowdoin and was graduated from the University of Vermont in 1897 He had been a practicing physician in New Hampshire since 1902

Dr Cogswell is survived by his widow and two daughters, Miss Maude Cogswell and Mrs Marion Harvell

CASE 22071

PRESENTATION OF CASE

A forty four year old Italian machinist was admitted complaining of a productive cough.

The patient had been perfectly well until six months before entry at which time he developed a slight head cold followed later by a nonproductive cough. At the end of the second week he was sent to a hospital where he remained until his admission here. During his hospital stay the cough remained constant and became productive of about two cups of yellowish sputum daily. For about five days, three months before admission, he had blood tinged sputum but at no time was there gross hemoptysis. For one month the sputum had been quite foul. During the first four months of his illness he had frequent night sweats but there were none thereafter. Six weeks before admission he developed sharp pain in the right axilla which was aggravated by cough and inspiration. The pain persisted for four weeks and then subsided completely. His appetite became capricious and his weight decreased from 168 to 128 pounds. He had frequent frontal and occipital headaches which continued for several days at a time. There were occasional sensations of chilliness and warmth. At times coughing would cause him to vomit.

The past history is noncontributory.

Physical examination showed a well-developed, somewhat emaciated, pallid man. The skin was moist and warm. The mucous membranes were pale and there were many carious teeth. The tonsils were large and ragged. The heart was negative. The blood pressure was 110/80. Flatness was elicited in the right upper chest anteriorly down to the level of about the fifth rib. In this region there were crackling râles, bronchial breathing and pectoriloquy. Posteriorly on the right side there were fine râles impaired resonance and pectoriloquy down to about the fifth rib. There was clubbing of the fingers. The reflexes were symmetrical but hyperactive.

The temperature was 98.2°, the pulse 120. The respirations were 28.

Examination of the urine showed a specific gravity of 1.006 to 1.010 but was otherwise negative. The blood showed a red cell count of 3,400,000, with a hemoglobin of 55 per cent. The white cell count was 8,700, 74 per cent polymorphonuclears. Repeated sputum examinations were negative for tubercle bacilli. The stools were negative. A Hinton test was negative. Intracutaneous tuberculin gave a positive reaction with 1:1000 dilution but with none of the higher dilutions.

X-ray examination showed a rather homogeneous dullness involving the entire middle lobe and part of the lower border of the right upper lobe. There were two areas of diminished density close to the upper border of the process.

Throughout the patient's hospital stay his temperature varied irregularly between 98° and 102°. It often continued several days without rising above 99°. His pulse remained elevated at 100 or over. On the eleventh day a bronchoscopy showed congestion and thin green foul pus in the right upper bronchus. He continued to expectorate considerable foul greenish sputum which on one occasion was bloody and contained a few small clots. Another x-ray showed a fluid level at the upper edge of the process and extension into the septum between the lower and middle lobes. Examination of the chest showed dullness from the angle of scapula to the tenth rib. Breath sounds were tubular in quality and showed slight diminution in intensity on the right side. Tactile fremitus was not diminished. Amphoric breathing was heard in the region of the right nipple. The heart was neither enlarged nor displaced. A second bronchoscopy showed pus exuding from the right middle lobe bronchus. One month after entry the intercostal bundles between the third and the sixth ribs were excised and one week later the fourth and fifth ribs were resected anteriorly. Four days postoperatively while the surgical dressing was being changed he suddenly began to cough up large amounts of blood. The hemorrhage could not be controlled and he died shortly afterwards.

DIFFERENTIAL DIAGNOSIS

DR. FREDERICK T. LORD: Will you demonstrate the x-rays, Dr. Hampton?

DR. HAMPTON: This is an oblique view showing dullness on the right side with an area of rarefaction in the upper portion. Here we see a very definite area of rarefaction in the anterior part of the lung. It seems to have a fluid level. Three or four weeks later an anteroposterior view shows dullness in the region of the middle lobe and the lower portion of the upper lobe. This shadow here is middle lobe and the cavity is in the upper lobe.

DR. LORD: There are no masses?

DR. HAMPTON: No masses or appreciable dis-

placement of the mediastinum that I can be sure of. The heart is over a little toward the right. There is nothing here which could be explained by a consolidated middle lobe and a cavity in the upper lobe on the right side.

DR LORD: The x-ray extends the information in a desirable direction inasmuch as there is no sharply limited shadow but the increased density fades into the neighborhood. The inter-spaces are no more narrowed than one might expect from an encroaching process.

DR HAMPTON: That is the posterior portion of the middle lobe, and up above the anterior margin of the lower lobe. The septum is convex upward and anteriorly, indicating that the upper lobe has been reduced in size, but that could be due to partial destruction of the lobe as well as bronchial occlusion.

DR LORD: The question of a pleural effusion may be raised. The signs are those of consolidation and not of pleural effusion, but encapsulated effusion may, nevertheless, be present. The signs of cavity are ordinarily absent in a disturbance of this sort and it is difficult to explain the presence of amphoric breathing in the region of the right nipple some distance away from the site of the cavity seen in the x-ray.

The symptoms come in sequence, with first a cold six months ago and later cough. We do not know exactly when he had sputum, but not until after the lapse of two weeks. Pain did not come until he had been ill for four and one-half months and the sputum was foul only after five months. Of course abscess is to be thought of, but this evolution of symptoms is unusual. With uncomplicated abscess we expect the complex of symptoms to be complete within a shorter space of time. Abscess is almost constantly peripheral and pain from invasion of the pleura ordinarily comes early in its course. The appearance of individual symptoms in sequence with long intervals between suggests the possibility that the abscess is complicated by something else.

We would like to know the severity of the headache. Cerebral abscess may complicate lung suppuration and the intensity of the headache may have a bearing on this question.

I have already commented on the physical signs, but it is always desirable to consider the possibility of bronchostenosis and atelectasis with which the signs are dullness, diminished or absent breathing, voice, whisper, and tactile fremitus. The signs here are not consistent with bronchial obstruction, the x-ray findings are against it, and we may conclude that here the bronchi, at least the larger bronchi, are probably open.

Clubbing of the fingers may be regarded as consistent with suppuration or malignancy or both. The blood findings with the low color

index are consistent with a secondary anemia, but it would be desirable to have a description of the blood smear. The absence of tubercle bacilli on repeated examination of the sputum is against tuberculosis. But it is desirable to have the sputum examined for such other organisms as streptothrix, actinomyces and blastomyces. A positive skin test with tuberculin is to be expected at this age.

Bronchoscopy should always be considered in the presence of localized lung suppuration. It does not seem necessary, however, to do it in all cases as a routine. It is especially indicated when from the history, the physical signs and the x-ray there is a suspicion of the presence of foreign body or malignancy. It may be of assistance in more accurately localizing a suppurative process for surgical intervention. Here it can hardly be said to have localized the process other than to indicate the presence of pus in the right upper and middle lobe bronchus. A difficulty with respect to localization by this means is that the exudate from an abscess may be aspirated into a neighboring or remote bronchus. Bronchoscopy is of little or no value in the treatment of abscess.

Now with respect to the diagnosis, in spite of the unusual evolution of symptoms, it seems reasonable to conclude that he has a lung abscess. There is nothing to suggest tuberculosis other than that the disease must be considered in all pulmonary lesions. The absence in the x-ray films of subapical mottling and the character of the increased density in the involved region are against tuberculosis and we can, I think, dismiss it as unlikely. The unusual evolution of symptoms makes it necessary to consider another possibility. The x-ray findings are not suggestive of malignant disease of the lung. With lung malignancy the increased density tends to be homogeneous with sharply limited margins and here it is mottled with rather ill-defined margins. Nevertheless, I do not think that the possibility of a hidden malignant disease can be excluded.

With respect to the abscess itself, I can go somewhat farther and say that in view of the long duration, the chances are that it consists of multiple though circumscribed areas of suppuration. The hemorrhage probably came from an eroded vessel. There is also the possibility, rather remote, of a complicating cerebral abscess or malignancy.

DR DONALD S. KING: The thoracic service struggled with this problem. We raised the question that Dr. Lord has raised as to whether the process was lung abscess following a pneumonia process or whether it was an abscess in association with malignancy. Although we did not feel that there was any definite evidence of malignancy, the patient was bronchoscoped in order to rule out such a process. I think that

we have had more so-called postpneumonic abscesses this year than usual, and we assumed that this was a lung abscess following an infectious process.

Dr. Lord There is nothing suggestive of a lobar pneumonia in the history.

Dr. King No

Dr. Fred This patient was bronchoscoped twice at an interval of fourteen days. Bronchoscopy was done to help in determining whether there was any new growth or abscess and if abscess in what lobe it was confined. No new growth, outcropping or foreign body was seen. At the first bronchoscopy a profuse amount of thin foam was seen to come from the right upper lobe. The middle lobe at this first bronchoscopy was absolutely clear. The pathology appeared to be confined from the bronchoscopic standpoint to the right upper lobe, but at the second bronchoscopy pus was seen to come from both the right upper and right middle lobes.

Dr. J. H. Means I wonder if the long continued story that Dr. Lord felt was atypical for acute lung abscesses might be due to a succession of abscesses. We see that occasionally I remember one patient who had x-rays from another hospital showing abscess on one side and when she came to us she had it on the other side. No doubt she had one that healed up and later had another. That might account for this kind of picture. There is a man with postpneumonic abscess on the ward at the present time. His course is not exactly like this but it is somewhat analogous. The question of cancer is interesting and I suppose it occurred to most of us. However, I should like to ask Dr. Mallory if he would not expect an abscess of this sort due to cancer to be peripheral to the cancer and the bronchoscopist really ought to see the cancer if that was the fundamental lesion here.

Dr. Tracy B. Mallory That is usually the case. I can remember one case however where the abscess had involved the cancer and eaten so much of it away that the bronchoscopist was unable to recognize it. We caught it only histologically and did not recognize it in gross.

CLINICAL DIAGNOSIS

Lung abscess

Dr. Frederick T. Lord's diagnoses

Lung abscess

Question of malignant disease

ANATOMIC DIAGNOSIS

Chronic pulmonary suppuration and fibrosis with necrosis and cavitation

Bronchiectasis right upper and middle lobes, slight

Pulmonary hemorrhage

Pulmonary emphysema

Operative wound First stage thoracoplasty

Pleuritis, chronic fibrous, bilateral

Arteriosclerosis, cerebral and aortic, slight

Pulmonary osteoarthropathy

PATHOLOGIC DISCUSSION

Dr. Mallory In this patient we found a process in the upper and middle lobes on the right which consisted of a very diffuse fibrosis of the entire lobe with multiple cavities all through it but the cavities appeared to be for the most part out in the pulmonary parenchyma, beyond the limits of the bronchi, so that we had to call them multiple abscesses rather than bronchiectases, although there were a few small bronchiectases. The cavities varied from a centimeter in diameter—there were a number as small as that—up to one three centimeters in diameter which was probably the one in which Dr. Hampton demonstrated a fluid level.

From the histologic point of view there is very little to help us in interpreting this case. It seems to me hopeless to trace the origin of the process. Perhaps the most striking thing was the degree of fibrosis in the regions where you would expect lymphatics, as though there had been a definite fibrosis of lymphatics. We see marked fibrosis of lymphatics in other conditions for instance in silicosis it is quite constant, but it can occur also in infectious processes. I think I would be a little inclined to Dr. King's suggestion that this might have followed a pneumonia although certainly the history does not give us any characteristic story to suggest that.

Dr. Lord I have been very loath to accept lobar pneumonia, if that is what you were thinking of.

Dr. Mallory No

Dr. Lord Our efforts to incriminate lobar pneumonia have largely failed. The early symptom complex with abscess is seldom that of lobar pneumonia. An origin of abscess in bronchopneumonia cannot be denied, and in a restricted sense this is probably true, putrefactive organisms giving rise to bronchopneumonic processes which break down into abscess.

Dr. Mallory You would regard it as essentially abscess from the start?

Dr. Lord Yes, regarding the tissue changes arising in consequence of a special type of infection and the development of abscess therefrom as an independent affection.

Dr. Mallory We do not know at all in these cases how often an infectious process which starts with a single organism such as bacillus mucosus or streptococcus may be complicated by multiple infections later but we have the analogy of an infarct, for instance, which may develop into an abscess.

The terminal event was a very profuse hemorrhage in the course of which he bled more

into the bronchial tree than he had into the surgical drainage wound. The entire bronchial tree in both lungs was completely plugged with clots of blood and on the left side there was the acute emphysematous dilatation of the alveoli one sees in a drowned man. Death unquestionably was from suffocation. That is a fairly common terminal event in these cases whether or not they are operated on.

CASE 22072

PRESENTATION OF CASE

A forty-five year old white American clerk was admitted complaining of generalized itching of the skin and painful nodules on the fingers.

Twenty-three years ago the patient became ill with painless swollen ankles which were followed by generalized edema. At this time he was admitted to a hospital where he remained for five months, during which period he gradually improved. He was not entirely free from the edema, however, until five months after discharge from the hospital, and it was almost a year before he could return to his work. Following this for about twenty years, except for nocturia of one time, he felt quite well. About two and a half years before entry he began to feel run-down and developed generalized itching and dry skin. He consulted an osteopath who examined his urine and told him that he had a mild diabetes and kidney disease. He was given injections of liver extract for four months "to build up his blood", and also a course of spinal manipulations which relieved his sense of fatigue. The itching was also lessened in intensity. Eleven months prior to admission he again returned to the osteopath for the same reasons he had given previously. He received weekly injections of liver extract thereafter. During this time his nocturia increased three to four times. Two months before coming to the hospital he had burning pain in the middle three fingers of his right hand, and nodules appeared over the skin in this region. Hot soaks relieved the pain but the nodules persisted. Shortly thereafter he developed a tender swelling upon the right elbow which persisted for about a week. He then had successive similar swellings in the region of the right shoulder, left shoulder, left elbow, and ulnar aspect of the left wrist. All these disappeared except the nodule on the wrist which occasionally afforded him some aching pain. Three weeks ago a firm, nontender nodule, about the size of a twenty-five cent piece, appeared on the back of his right elbow. At no time was there any flank joint involvement. His weight had remained constant for three years.

He had scarlet fever at ten years of age.

Physical examination showed a thin pallid man in no acute distress. The patient was ambulatory and cheerful. The skin had a sallow yellow ochre hue. The retinal arterioles were narrowed and shining and there was what appeared to be an organizing hemorrhage in the left retina. The heart was not enlarged. A rough systolic murmur was heard all over the precordium and a prolonged diastolic murmur was audible at the apex. The blood pressure was 165/90. The liver edge was at the costal margin. The prostate was symmetrically enlarged, firm and smooth. The peripheral vessels were firm, nodular and tortuous. There were several cystic swellings about the proximal interphalangeal joints of the right forefinger some of which were translucent and others opaque.

Examination of the urine showed a specific gravity of 1.008, with a trace of albumin and a green reaction to Benedict's solution without precipitate. The sediment contained an occasional white blood cell and a rare red blood cell and granular cast. The concentration test showed a specific gravity fixation between 1.010 and 1.012. The blood showed a red cell count of 3,800,000, with a hemoglobin of 65 per cent. The white cell count was 12,000, 63 per cent polymorphonuclears. There was no stippling and the platelets appeared to be normal. A Hinton test was negative. The nonprotein nitrogen of the blood was 120 milligrams. The carbon dioxide combining power was 37.8 volumes per cent, the uric acid 4.4 milligrams per cent. The chlorides were equivalent to 107 cubic centimeters N/10 sodium chloride. The serum protein was 4.9 grams per cent. A phenolsulphonephthalein injection showed less than 15 per cent of the dye excreted in one hour. A fasting blood calcium was 10.10 milligrams. The phosphorus was 7.92 milligrams and the phosphatase 9.36 units. A stool examination was negative. An electrocardiogram showed normal rhythm with slightly diphasic but essentially upright T_2 and T_3 . Q_4 and T_4 were negative.

X-ray examination showed masses of homogeneous calcification without trabeculation surrounding the proximal interphalangeal joints of the right second, third and fourth fingers. Similar calcified areas were scattered along the phalanges of these fingers. The cortex of some of the phalanges was thin and moth-eaten in appearance. Both elbows showed similar calcified masses overlying the distal metaphyses of the humeri. The cortex of the radius in the region of the tuberosity and the proximal ends of both humeri showed haziness. There were similar calcified areas about the acromioclavicular joints. These were also present in the soft tissues proximate to the pedal phalanges. The tibiae and fibulae were not remarkable. The

bones of the pelvis showed slight decalcification. The heart contours were at the upper limit of normal and there was a questionable enlargement of the left ventricle. The skull was riddled with small areas of decalcification, one larger area measuring 1.5 by 1 centimeter. In all of the films the large and small vessels showed a marked degree of arteriosclerosis with calcification, some of them definitely of the Monckeberg type. A pyelogram showed the kidneys to be extremely small. They secreted very little of the dye. The jaws showed absence of lamina dura about most of the tooth sockets and the bone was radiolucent and said to have a ground glass appearance. In some regions there was definite thinning of the bone. Very few canines were seen in the teeth.

The patient continued to be remarkably alert and active for the amount of azotemia he showed. One observer noted urinous odor to his breath. At the end of two weeks he developed a severe diarrhea and had several nose bleeds. This continued for about two days. Shortly afterward the serum calcium was found to be 9.13 milligrams, the phosphorus 7.0 and the phosphatase 4.5 Bodansky units. An arterial blood analysis of the acid base components showed an approximate pH of 6.95. The blood showed a red cell count of 296, with a hemoglobin of 60 per cent. A few days later under local anesthesia a tibial biopsy was done. Shortly thereafter the patient began complaining of malaise and appeared to be quite apprehensive. Four days postoperatively he was suddenly seized with severe pain between the shoulder blades which later was localized in the left anterior chest and upper abdomen. There was some radiation down the left arm and associated dyspnea and orthopnea. The radial pulse became imperceptible. The blood pressure was 60/50. The heart sounds were poor and a gallop rhythm was heard. There was slight dullness at the left base and a few crackling rales in the same region. The temperature which had previously been normal rose to 99.8°. An electrocardiogram showed a left bundle branch block. T₁ was inverted, T₂ was upright. The P-R interval was 22 seconds. The Q-R-S was 18. The rhythm was slightly irregular, the rate 60. Lead four showed wide excursions and Q₄ was nearly absent. R₄ was plus 30 and T₄ minus 22. His condition remained unchanged and he died five hours later one month after admission.

DIFFERENTIAL DIAGNOSIS

DR. CHESTER S. KLEFEL.* From this patient's history the physical findings, and the course of the disease, it would appear that there were two main diagnostic problems. (1) The nature of the renal lesion associated with metastatic calcification and calcinosis. (2) The ex-

*Associate Physician, Thorndike Laboratory of the Boston City Hospital.

planation of the episode that caused the patient's death. I shall discuss this case under these two headings.

When a patient presents the clinical features of renal failure and metastatic calcification with or without calcinosis one considers the following conditions:

- 1 Primary hyperparathyroidism with nephrocalcinosis, or pyelonephritis with urinary calculi.

- 2 Chronic pyelonephritis or chronic glomerulonephritis with secondary hyperparathyroidism (renal rickets—chronic pyelonephritis with contracted kidney).

- 3 Calcinosis and chronic nephritis without evidence of parathyroid hyperplasia.

- 4 Primary bone disease with amyloidosis of the kidney, pyelonephritis or tubular atrophy (multiple myeloma).

I feel reasonably certain that one can exclude the possibility of a multiple myeloma in this case, so that I can take up the discussion of the other conditions at once.

Let us review the salient points in the clinical record. In brief, the patient was a man forty-five years of age who entered the hospital on account of pruritus and painful nodules on the fingers. At the age of ten years he had scarlet fever which may or may not have been accompanied by interstitial and focal glomerulonephritis, however, from the data available, the first indication of a disorder of the kidneys was a generalized edema which lasted for about ten months. He was then twenty-two years of age. Following this experience he remained reasonably well for twenty years, when he developed a feeling of malaise and generalized pruritus with dryness of the skin. Excretion of his urine at that time (two and a half years ago) revealed evidences of kidney disease and mild diabetes. There was a temporary remission of his symptoms of fatigue but nocturia increased. Two months before entering the hospital he noticed painful nodules appearing in the skin of the fingers, later there was swelling over the right elbow, then swellings about other joints of his body.

The examination revealed a thin, pale man with a sallow yellow skin, retinal arteriolar sclerosis with an organized hemorrhage in the retina, slight hypertension without cardiac enlargement, a rough systolic murmur over the precordium and a diastolic murmur at the apex. There were cystic changes about the proximal interphalangeal joints of the right forefinger.

The laboratory examinations revealed albuminuria, and only occasional leucocytes, erythrocytes or casts in the sediment. There was a slight secondary anemia with a moderate leucocytosis. Renal functional studies revealed a loss of concentrating power, nitrogen retention, decreased phenolsulphonephthalein excretion. There was a phosphate retention, a re-

duced CO₂ combining power, a low pH, a slight reduction in the serum proteins, a normal blood calcium and an increased blood phosphatase. X-ray examinations revealed calcification in the subcutaneous tissue about the fingers, elbows, acromioclavicular and toe joints, decalcification of the skull, pelvic bones, phalanges, radii and humeri. There was extensive calcification of the blood vessels, and the kidneys were extremely small without x-ray evidence of stones or calcification.

X-RAY INTERPRETATION

DR AUBREY O HAMPTON There is a large area of calcification behind the lower end of the humerus which extends to the joint and farther upward than you would expect the joint to extend. The bones are decalcified, and here you can make out subperiosteal bone absorption or bone destruction. This is a very unusual finding in any disease excepting those associated with parathyroid abnormalities and we consider it one of the most characteristic findings of parathyroid abnormality. The skull shows fine areas of increased and diminished density which produce a mealy appearance of the bone with obliteration of blood vessel channels, diploe, and all the normal structures, and with perhaps some thickening of the bone.

This plate of the leg shows extensive calcification in the blood vessels. Furthermore, as has been pointed out by Dr Schatzki [I do not think he did the original work], this calcium is arranged in concentric circles so that you can deduce from the x-rays that it is in the media of the artery. This plate of the hand shows further deposits of calcification around the joints and here the calcium is definitely outside of the joint in the anterior aspect of the palmar tissue of the fingers. These bones also show decalcification and some subperiosteal absorption. The blood vessels in the wrists and the fingers are also markedly calcified. There are no cysts in any of the bones. The kidney outlines are very small.

DIFFERENTIAL DIAGNOSIS CONTINUED

DR KEEFER In brief, then we have a man with a chronic progressive renal failure who finally develops signs of calcinosis and calcification in his blood vessels. This picture fits in very well with a few cases that have been described in the past (Hubbard and Wentworth, Fontana, Penedee). That is to say, patients who have had symptoms of chronic renal disease for varying periods of time (several months to nine years) finally develop metastatic calcification and calcinosis with decalcification of the skeleton. It apparently has been a little more common to observe the same picture *without* calcinosis in the presence of chronic renal disease. Now, in view of the fact that patients with chronic nephritis and metastatic calcification may have enlargement of

one or more of the parathyroid glands the interpretation of the sequence of events in these cases has given rise to lively and interesting discussion. There are undoubtedly cases in which the hyperparathyroidism *precedes* the renal failure and metastatic calcification. These are instances of primary hyperparathyroidism with pyelonephritis and urolithiasis or nephrocalcinosis—so ably defined and described by Albright and his associates as Types 1 and 2.

In addition to these cases, there are instances in which the renal failure precedes the signs of skeleton demineralization and metastatic calcification, and there seems to be little question that in some of these cases, at least, there is secondary hypertrophy of the parathyroid glands and evidences of hyperactivity. From the chronological data in the history and clinical course, I believe that the present case belongs in this group, namely, chronic renal insufficiency with secondary hyperparathyroidism and subsequent metastatic calcification and calcinosis.

I should outline the sequence of events as follows: the development of chronic nephritis with renal insufficiency, the retention of phosphates, enlargement of parathyroid glands with increased activity, demineralization of skeleton due to increased parathyroid activity, chronic acidosis and loss of calcium phosphate in the stools, and finally the precipitation of calcium phosphate and perhaps carbonate in the tissues of the skin and internal organs.

There is an isolated case on record of calcinosis, and calcification in the various blood vessels and tissues associated with scleroderma, in which death resulted from renal failure without nephrocalcinosis, hypertrophy of the parathyroid glands or demineralization of the skeleton. In view of the fact that this patient did not have scleroderma or calcinosis before the signs of renal failure, it seems fair to exclude this type of case from consideration.

Now, a word regarding the nature of the renal lesion in the present case. There are three types of renal disease with a prolonged course such as was evident in this patient, chronic diffuse glomerular nephritis, chronic pyelonephritis with contracted kidney and congenital cystic kidneys. The latter condition can be excluded at once on account of the absence of attacks of gross hematuria, or of bilateral masses in the flanks, and by the evidence of small kidneys by pyelogram. The history of the onset of the renal disorder with edema suggests glomerular nephritis rather than pyelonephritis, although it is a little unusual, but by no means unknown, for patients with chronic glomerulonephritis to have such a long course, especially when hypertension and endarteritis obliterans are minimal. I should favor a diagnosis of chronic diffuse glomerulonephritis.

There remains for brief discussion the episode

which caused death. There was a sudden onset of thoracic pain, radiating down the arm with the signs of acute heart failure and peripheral vasomotor collapse, the development of a bundle branch block, dullness and rales at the left base of the lung, and death within five hours. This suggests a coronary occlusion, or a pulmonary embolism. In view of the pain and its distribution, the sequence of events and the absence of a definite source for an embolus I should favor a coronary occlusion rather than a pulmonary embolus.

CLINICAL DISCUSSION

DR. FULLER ALBRIGHT. Dr. Keefer has taken the wind entirely out of my sails. He discussed almost everything I had to say.

There is one interesting point, as you look at this complicated picture with those extraordinary calcified masses around the joints, renal insufficiency, decalcification, and so forth you wonder if it is one disease. The fact remains that it is because I know of two other patients who had the same thing, that is long standing renal disease, calcium deposits around the joints, marked demineralization suggesting hyperparathyroidism, and arteriosclerosis of the media of the arteries. The other cases came to autopsy and did show enlargement of all the parathyroid glands and bone changes typical of osteitis fibrosa cystica, not osteomalacia. The disease, therefore, is analogous to renal rickets etc. The only difference is that renal rickets occurs in children and there are changes of the growing cartilage in addition. These changes look like rickets by x ray but turn out not to be rickets under the microscope. The condition is really osteitis fibrosa cystica occurring in growing children.

My diagnosis on this patient before he came to Dr. Mallory's department was the same as Dr. Keefer's and I expected to find four enlarged parathyroid glands.

I would like to say one word about three different types of conditions which may be confused now in everybody's mind. (1) Parathyroid adenoma which leads to hyperparathyroidism, with increased calcium and phosphorus in the urine and hence to renal disease. That is one clear entity which everyone has firmly in mind. (2) The second entity starts with renal disease and leads to phosphorus retention and compensatory hyperparathyroidism. We do not know how it gets there but you also have decalcification of the skeleton in this syndrome. The end result is different from the first but not very much. The one main difference in the second type is enlargement of all four parathyroid glands instead of one adenoma as in the first type. It would be very easy to differentiate the two if it were not for the fact that

there is a third entity. (3) This starts with hyperplasia of all the parathyroids and results in hyperparathyroidism, with increase of calcium and phosphorus in the urine and changes the same as with the first. We have therefore two conditions with four enlarged parathyroids and one condition with one enlarged parathyroid. The two with the four enlarged parathyroids fortunately can be differentiated very easily from each other because where the hyperplasia starts as a primary hyperplasia (it is obviously secondary to something else, but primary as regards the kidney) the histology of the parathyroid tissue is quite different from what it is when the hyperplasia is secondary to renal disease.

It might be worthwhile to theorize a little as to what is the sequence of events that leads to the condition we have before us today. In the first place it unquestionably starts as renal disease—it is only with long standing renal disease over a period of ten or fifteen years that you get the complete picture. The phosphorus retention is probably the next link in the chain. I believe this is the stimulus causing the parathyroid glands to become hyperplastic. Phosphorus retention tends to lead to a low blood calcium and a low blood calcium stimulates the parathyroids to enlarge. That would explain the enlarged parathyroids but would not explain why you get bone disease. Why you get the bone disease I do not know. There are two possible ways. In the first place it may be caused by an increased amount of hormone going directly to the bone and causing bone disease. This explanation is reasonable if one believes that the hormone acts in bone tissue. That is not my personal belief. The other possibility is that the bone disease is entirely due to the marked acidosis you see with this condition. This patient, with a CO_2 combining power of only twenty eight had an extreme acidosis which I hope Dr. Talbott will discuss later. He did a complete electrolyte balance on the patient. We know acidosis will cause changes in the bones of the same nature as those seen in hyperparathyroidism.

DR. JOHN H. TALBOTT. If our assumption is correct that the first and primary condition was chronic nephritis, I think it interesting that the duration of the disease should be as long as it was. Twenty two years ago this patient was hospitalized and treated for chronic nephritis. In the intervening years he had been able to carry on his work in a most satisfactory manner. After admission to this hospital we were able to obtain one sample of arterial blood for analysis of the acid base constituents. There is no rule of thumb whereby in a given patient with a disturbance of the electrolyte balance we can predict the concentration of any one constituent. Hence, we consider the following

to be the irreducible minimum number of determinations to be done to give us an accurate picture of the internal environment of a patient. These determinations are carbon dioxide, chloride concentration, sodium and protein concentration and nonprotein nitrogen.

This patient on examination of his arterial blood had a severe acidosis and the carbon dioxide content of the serum was only twenty-eight volumes per cent or approximately twelve milliequivalents, about half the normal. The chloride concentration in spite of the severe nephritis was normal. The sodium concentration of the serum was only 127 milliequivalents, a decrease of about 12 milliequivalents below the normal. Referring again to the carbonate concentration we remember that this was down about 12 milliequivalents, therefore the principal disturbance was a lowered sodium and carbonate concentration with a normal chloride concentration.

The interesting thing in this patient to me, as far as the disturbances of the acid base equilibrium are concerned, is what we would have done had we seen this patient and made these studies ten or fifteen years ago. It is conceivable that if we had found such a disturbance in a mild degree we might have been able to relieve or prevent the acidosis, which I assume to have been responsible for the long train of symptoms leading up to this particular type of hyperparathyroidism. I am interested in this patient as an example of what might be done regarding the preventive aspect of one of the rare manifestations of the terminal stage of chronic nephritis.

CLINICAL DIAGNOSES

Chronic glomerulonephritis
Coronary thrombosis?
Dissecting aneurysm?
Rheumatic heart disease?
Aortic regurgitation

DR CHESTER S. KEEFER'S DIAGNOSES

Chronic glomerulonephritis
Renal insufficiency
Hypertrophy of the parathyroid glands (secondary hyperparathyroidism)
Demineralization of the skeleton
Metastatic calcification with calcemosis
Calcification of the mitral valve producing the cardiac murmurs
Coronary occlusion

ANATOMIC DIAGNOSES

Chronic glomerulonephritis
Secondary parathyroid hyperplasia, marked
Rheumatic heart disease with calcification of the mitral and aortic valves and with mitral stenosis and aortic regurgitation
Coronary occlusion

Myocardial infarction
Calcification of the coronary arteries and peripheral vessels
Arteriosclerosis, marked aortic
Osteitis fibrosa of the skull
Calcified nodules of the elbow, fingers and shoulder
Hydrothorax, bilateral
Pulmonary edema, bilateral, slight
Ascites, slight

PATHOLOGIC DISCUSSION

DR TRACY B. MALLORY: The autopsy on this man substantiated in practically every detail the clinical diagnosis. We found an extremely atrophic pair of kidneys, weighing only 85 grams. They were granular as well as small, and the cortex was reduced to only 2 mm in width. Microscopically they show an extreme grade of atrophy, some persistent glomerular scars, and foci of dilated hyperplastic tubules. The pelvis are entirely negative and I think it is possible to rule out flatfootedly any question of chronic pyelonephritis. We feel quite sure this is chronic glomerulonephritis.

The next most interesting finding of course concerned the parathyroids themselves. All four of them were very much enlarged and practically popped into view with almost no dissection. The smallest of the glands weighed two grams and the largest nearly five. We estimated the total weight of the four glands as eleven grams. They were interesting in appearance furthermore because they did not look like any parathyroids that we have seen before. On cutting across them they were perfectly homogeneous cream-colored, and so nearly cheesy that I wondered if we might not find necrosis or caseation. They did not have the characteristic orange color that ordinarily enables one to identify parathyroid tissue. On microscopic examination we found a very diffuse hyperplasia with all the cells of the small "chief cell" variety, practically nowhere throughout the four glands have we found any cells with the abundant, highly vacuolated cytoplasm usually described as "water clear" cells. In what we have chosen to call primary hyperplasia with hyperparathyroidism all the cells are of the "water clear" variety so we have here a very sharp histologic difference. It is interesting that with a glycogen stain this patient's glands showed a more intense reaction than any other parathyroid tissue we have examined whereas the primary type of hyperplasia usually shows very little glycogen.

This is a postmortem x-ray of the spine. It shows very prettily the herniation of the intervertebral discs into the bodies of the vertebrae through the softened cortical layer of the vertebral body.

As to the other findings, the vessels throughout the body were of course very extensively calcified. That is particularly true of the larger vessels of the leg which show a typical Mönckeberg type of medial calcification. It was also true of the coronary arteries. They show an extreme grade of calcification with atheromatous deposits and marked narrowing of the lumen. We found in the coronary arteries at autopsy a fresh clot and we were unable to decide whether it was ante- or postmortem. The right auricle of the heart also contained a fresh looking clot which seemed a little too adherent for postmortem clot but again we could not be sure whether it was ante- or postmortem. The microscopic

examination, however, clears up the point completely because there are foci of definite early infarction of the myocardium which we were not able to make out grossly, so the clinical diagnosis was more correct in that respect than our gross autopsy findings. The heart showed also, as was predicted, typical rheumatic valvular disease with both aortic and mitral involvement.

The bones showed distinct softening. The skull was thickened, cut very easily, and the diploë was practically indistinguishable from the cortex. Microscopically the changes were indistinguishable from those of true hyperparathyroidism.

"DRUG TO END PAIN IN ANGINA REPORTED"

So ran a headline on the first page of the *New York Times* for the last day of 1935. The Professor of Pharmacology at the University of Maryland had read a paper before the American Association for the Advancement of Science at St. Louis. The drug reported was trichlorethylene.

Trichlorethylene is a highly volatile liquid with a strong, sweet smell, first used as a commercial solvent and varnish, and thus found to produce a curious syndrome in some of the workers who handled it. Among its symptoms were vertigo, nausea and anesthesia of the trigeminal nerve. For some years past it has been used for the relief of trigeminal neuralgia, fifteen to twenty drops being inhaled from a handkerchief until the odor has disappeared, and repeated three or four times a day. Too large or frequent dosage has been thought by some to produce disorientation, acute yellow atrophy of the liver, and even ventricular fibrillation with sudden death. Others, however, have denied its toxicity. There is no question

that trichlorethylene does produce vertigo and it should therefore be inhaled, like amyl nitrite, in the recumbent position.

Because of this vasodilating effect, it is not surprising that trichlorethylene has been found to relieve "fifteen out of twenty cases", although the number of cases of angina to be relieved by any treatment will depend largely upon the diagnostic criteria used. What is surprising in the *New York Times* account is that "one cubic centimeter in crystalline form, inhaled as snuff, was said to relieve attacks in one second".

The excursions of the daily press into the medical and scientific worlds should not be read too critically. Those of us who are free to come home from a medical meeting and decide that there is nothing of significance among the novelties of the day have a freedom which is denied to the news reporters. So many people having learned to read—they must be furnished with reading material. Medical progress is good reading material, but in the daily press it must be sufficiently sensational to compete with the highly dramatized news of the day—political, criminal and social. Hence the tendency to make a complete symphony out of a perfectly good folk-song.

Trichlorethylene will prove, we hope, a useful drug for the purpose here announced. We only wish that by ending the pain of angina we could solve the many problems that underlie it.

The Massachusetts Medical Society

SECTION OF RADIOLOGY AND PHYSIOTHERAPY

The Section of Radiology and Physiotherapy of the Massachusetts Medical Society will meet at Springfield on Monday, June 8, at 2:30 P.M. There has long been a feeling among the workers in these specialized fields that neither the scope nor the limitations of their work were fully understood by the men in general practice. The program of the Section has therefore been planned to facilitate a better understanding along these lines.

"The Limitations of the Roentgen Method of Diagnosis." Why is the negative Graham-Cole test not worth 100 per cent in excluding gall-bladder disease? Why cannot an osteomyelitis be diagnosed in its incipency? Why are some fractures missed by the most careful technic? These and other questions of the sort will be discussed by Dr. Harvey W. Van Allen of Springfield, well known in his specialty for many years.

"What May the General Practitioner Expect of Physiotherapy?" This subject will be considered by Dr. Claude L. Payzant of Boston, Director of Physical Therapy at Quincy City

Hospital Some physiotherapeutic methods are overestimated, others are not so well known as they should be. Dr Payzant will endeavor to evaluate the entire subject with a view to the standpoint of the man in general work.

The subject of Birthmarks is important and interesting to every man who deals with babies. Much progress along this line has been made in recent years much of it seems not to have reached the rank and file of the profession. The modern treatment of these embarrassing and disfiguring lesions will be discussed by Dr J Harper Blaisdell of Boston. Dr Blaisdell was one of the first workers in this section to apply radium in dermatological work. He is a member of the Massachusetts General Hospital Staff and has occupied several teaching positions.

There will of course be discussion open to all, and it is hoped that many members outside the Section will take part.

THE ISSUE WHY DOES MASSACHUSETTS NOT PROTECT ITS CITIZENS?

In the midst of the discussion of House Bill 34 where one observes some lack of restraint, relatively few persons realize what is at stake, or are aware of the issues involved. If one reviews the arguments which have been presented to legislative committees in the past, omitting a multitude of irrelevancies they seem to run about as follows. There is a 'medical trust', which seeking power for itself rather than the welfare of the people, desires to destroy all medical schools which refuse to do its bidding. This trust controls all the state boards of registration in the United States, even the Massachusetts board, and all the medical schools except a few, which few in the spirit of independence and devotion to freedom, 'poor but honest', manage to hold out, especially in Massachusetts, the birthplace and home of liberty.

It would doubtless come as a surprise to the various state boards and to the many infinitesimal universities in the United States, both state institutions and those which are privately endowed, to learn that a medical trust controls them all by some malicious subconscious control it must be.

The second argument is that medical education has become so expensive through the efforts of the medical trust, that the poor boy cannot get an education in the schools which the trust controls, and therefore the 'independent' schools must continue to give opportunity for these poor boys. The fact that a comparatively well endowed medical school has available each year about forty thousand dollars for students who need financial aid, while the 'independent' school has nothing for such purpose, and yet makes approximately the same annual charge

for tuition is regarded as having nothing to do with the case.

These two arguments alone, though protean in form, are the stock in trade of the opponents of the Bill the right of the school to do as it pleases and the right of the poor boy to get a medical education!

There is a false philosophy implicated here, in the first place in emphasizing rights without qualification. Whose rights are involved, merely those of the school and of the poor boy? And why merely because the school wishes to please itself, and because the boy is poor?

The true philosophy begins with the consideration of duties which constitute the cause of rights. A medical school conferring degrees by authorization of the state, and by the requirements of the statute participating in the preparation of candidates for licensure, is no longer a purely private institution it is quasi public with duties commensurate with its function. Its right to do as it pleases is not unqualified, it is restrained in the interest of the public in accordance with its prescribed function. If its function is perverted by commercial interest, the chief temptation, it becomes the duty of the state to correct this perversion and to prevent degradation. The reason why the commercial interest is the chief temptation is because the state, by requiring the medical degree as a prerequisite for earning a living in the practice of medicine, has placed a commercial value on the degree.

That the 'poor' student has a right to medical education no one questions. Yet it is not an absolute right but qualified by several considerations. In the first place he may not want it, perhaps someone else has insisted on his studying medicine. In the second place he may not have adequate intelligence for it or he may be gifted, but not in the sphere which would make for success in medicine. Or he may not have enough money to pay for it. Whose obligation is it to see that he gets enough money? If there is detected any obligation to give him a medical education, there goes with it an obligation to give him an education worthy of the name, not a mere pretense. The issue is clouded with sophisms, by misrepresentations, by misunderstood facts, duties, obligations, responsibilities.

Yet the issue should be clear to all. It is the duty of the state to protect the citizens in matters affecting their health and against unqualified practitioners there is especial need. Why does the legislature of Massachusetts refuse to give the citizens of this Commonwealth as much protection against unqualified practitioners as the legislatures of other states give their citizens? Here is the issue, and the question is one which will be asked with increasing insistence until the answer is given. It is the duty of the citizens to find the answer.

ANALGESIA DURING LABOR

Definite progress has been made in the study and use of analgesics during labor within the past two or three years. The work, published in 1934 by Dr Irving and his associates and dealing with various types of obstetrical analgesia, was very complete in that it gave an excellent comparison of various combinations of drugs which may be used to alleviate pain during labor. Since the publication of this material, there has been a general increase in the use of the barbiturates, chiefly in the form of pentobarbital or nembutal. There has also been much discussion even to the claim that obstetrical analgesia increases maternal mortality. This has not been true at the Boston Lying-in Hospital, since the maternal mortality for 1934 and 1935 has been lower than previously. Practically all the patients were given pentobarbital during labor over this period. It must be remembered that here doctors specializing in obstetrics are ordering the medication and that certain necessary measures for safety are always available.

The purpose of this article is to impress upon the general practitioner certain points to be remembered when administering pentobarbital or nembutal for the purpose of amnesia during labor. In the first place these patients must never be left alone, even for a single second. They are not responsible and may fall out of bed, or in some way injure themselves. Some patients become very restless and measures must be taken to control them. Naturally, therefore, we feel that these drugs should not be used in the home or in any hospital which is not equipped to handle such a case.

The barbiturates, I believe, increase the incidence of vomiting and mucus. To be sure, this does not happen in every case, but when it does occur the general anesthesia given at the end must be administered by a very competent anesthetist. If not, the patient may aspirate mucus or vomitus which may prove disastrous. This is an extremely important point, and when excessive mucus occurs, in spite of atropine, general anesthesia had best be eliminated. The amount of vomiting is often in relation to how recently

*A series of short selected articles by members of the Section is being published weekly. Comments and questions by subscribers are solicited and will be discussed by members of the Section.

the patient has eaten and if this is considered when ordering the drug it would seem advisable to give it rectally rather than orally. In cases that enter labor vomiting, I believe it best not to give it at all.

As was pointed out in Irving's work, more babies have to be resuscitated than when no analgesia is used. These babies often have a moderate amount of mucus, and the obstetrician must always be prepared to remove the mucus. It can usually be done by the use of a simple catheter. This is very necessary in order that there be a clean airway before the usual methods of resuscitation are tried.

In spite of the occasional presence of such complications, this form of obstetrical analgesia can be used with safety provided the usual precautions are taken. There is no question that the use of these drugs has decreased the unnecessary use of forceps and manual dilatation. The writer believes that practically all the obstetricians familiar with this drug will agree to this.

Purposely, only the more important complications have been mentioned and, for more detailed information, the writer would advise reading the article written by Irving in 1914 and published in *Surgery, Gynecology and Obstetrics*.

MISCELLANY

THE APPOINTMENT OF DR. M. J. ROSENAU

Dr. Milton J. Rosenau who retired last February as professor of preventive medicine and hygiene in the Harvard Medical School and professor of epidemiology in the School of Public Health, has been appointed director of a new Division of Public Health, established as a part of the Medical School of the University of North Carolina. The purpose of organizing the department is to train students to be health officers. The department was founded by the University with the cooperation of the North Carolina State Board of Health.—*Science*.

MAINE NEWS

At the Thayer Hospital in Waterville a semi-annual review of mortalities has been instituted and adds much to the value of the staff meetings. These mortalities are critically analyzed from the point of view of mistakes in diagnosis, errors of judgment, technical errors and the diseased condition of the patient. Critical reviews and following are held on all cases which are discharged from the hospital with unsatisfactory results. These frank analyses of cases have stimulated much interest among the medical men in surrounding towns and result in a large and enthusiastic attendance at the Thayer Hospital staff meetings held fortnightly on the second and fourth Thursdays of each month.

ANDROSCOGGIN COUNTY MEDICAL ASSOCIATION

At the last meeting of this association it was frankly admitted that doctors in general are not well enough acquainted with the very important and nationally discussed topic of State or Socialized Medicine. It was suggested that in order that the profession become more familiar with the subject and able to discuss it more intelligently someone who has had the time to study and who knows the proposition from the doctor's point of view should be asked to present it. We were fortunate in securing the cooperation of Professor Brooks Qnimbry of Bates College who readily agreed with the suggestion.

This permitted us to prepare the following program for our first meeting of 1936 which was held in the Municipal Court Room City Building Lewiston on Thursday January 16 1936 at 8 30 P.M. Subject A formal debate by four members of the Bates Varsity Debating Squad on "Resolved That the several states should enact legislation providing for a system of complete medical service available to all citizens at public expense."

All members of the profession were cordially invited to attend and take part in the general discussion after the debate.

R. A. BELIVEAU M.D. Secretary

CUMBERLAND COUNTY MEDICAL ASSOCIATION

At the annual meeting of the Cumberland County Medical Association in Portland, Maine, on December 19 1935 Dr. Shields Warren of Boston read an extremely interesting paper on "Pathology of Malignant Diseases with Relation to Treatment."

Kennebec County Medical Association

At the annual meeting of the Kennebec County Medical Association held in Augusta on December 19 1935 Dr. Augustus Riley of Boston read a paper illustrated with lantern slides on the subject "Pain in Relation to the Kidneys." This paper was interestingly received and actively discussed.

Edward H. Risley M.D.

THE APPOINTMENT OF SIR FREDERICK HOPKINS

Sir Frederick Gowland Hopkins, British Nobel prize winner in medicine one of the world's leading biochemists and a pioneer in the field of vitamin research, has been appointed to the Harvard faculty for the academic year beginning next September. He is now the Sir William Dunn Professor of Biochemistry at the University of Cambridge and has been Professor of Biochemistry there since 1914.

At Harvard he will deliver a series of three lectures in the Medical School, as the Edward K. Dunham annual lecturer. The Dunham foundation was established in 1923 for the promotion of the medical sciences, through a gift of \$50,000 from Mary Dows Dunham in memory of her husband. A graduate of the Harvard Medical School in 1836. Holders of the lectureships are drawn chiefly from among

the leaders of foreign medical research and are selected by a committee of Harvard departmental chairmen. The foundation was designed to promote understanding between students and investigators here and abroad.

In 1906, Sir Frederick, working with W. Fletcher, laid the foundation of present knowledge of the chemistry of muscular contraction by his researches into lactic acid production in muscle. In the same year he published preliminary reports of experiments involving "pure diets," which proved the existence of essential amino acids, and of those accessory factors in foods which were afterwards to be known as vitamins. The full results of his vitamin work were published in 1912.

One of his later contributions, made in 1921, was the isolation from living tissues of the sulphur containing dipeptide glutathione, and the proving of its great importance for the oxidations in living cells.

He has also done outstanding work in animal pigmentation. He was awarded the Nobel prize in 1929.

AN HONOR TO DR. KARL BOWMAN

On January 30, 1936, a farewell dinner was given at the Hotel Brunswick to Dr. Karl Bowman, formerly chief medical officer of the Boston Psychopathic Hospital, who has left Boston to take up his new position as Director of the Bellevue Psychopathic Hospital in New York.

About one hundred persons representing his friends and associates attended the dinner.

Dr. C. Macfie Campbell acted as toastmaster. Entertainment in the form of an original dramatic sketch was furnished by some members of the Boston Psychopathic Hospital Staff, including Drs. S. H. Epstein, G. B. Pearson, J. H. DeShon, H. Hirning, R. Schwab, H. C. Solomon, R. H. Guthrie, F. L. Wells and Frances Hannett.

rank and file of the medical profession in the practice of preventive medicine. He was mindful of the significance and importance of a clean water and milk supply and did everything to encourage high standards in these vital essentials to everyday life. He championed strongly the extension of the Tuberculosis Clinics on a city-wide basis, so that there might be made available facilities for the very early recognition of the disease.

His genial nature, his warm smile, and his fine character endeared him to us all, and we join with his army of friends in expressing deep sympathy to his family and grateful appreciation of his unselfish services to the City of Boston.

ANNOUNCEMENT OF THE FRANCIS AMORY SEPTENNIAL PRIZE OF THE AMERICAN ACADEMY OF ARTS AND SCIENCES UNDER THE WILL OF FRANCIS AMORY

In compliance with the requirements of a gift under the will of the late Francis Amory of Beverly, Massachusetts, the American Academy of Arts and Sciences announces the offer of a septennial prize for outstanding work with reference to the alleviation or cure of diseases affecting the human genital organs, to be known as the Francis Amory Septennial Prize. The gift provides a fund, the income of which may be awarded for conspicuously meritorious contributions to the field of knowledge "during the said septennial period preceding any award thereof, through experiment, study or otherwise in the diseases of the human sexual generative organs in general." The prize may be awarded to any individual or individuals for work of "extraordinary or exceptional merit" in this field.

In case there is work of a quality to warrant it, the first award will be made in 1940. The total amount of the award will exceed ten thousand dollars, and may be given in one or more awards. It rests solely within the discretion of the Academy whether an award shall be made at the end of any given seven year period, and also whether on any occasion the prize shall be awarded to more than a single individual.

While there will be no formal nominations, and no formal essays or treatises will be required, the Committee invites suggestions, which should be made to the Amory Fund Committee, care of the American Academy of Arts and Sciences, 28 Newbury Street, Boston, Massachusetts, U S A.

THE JOURNAL CLUB OF THE DEPARTMENT OF OBSTETRICS, HARVARD MEDICAL SCHOOL

The monthly meeting of the Journal Club of the Department of Obstetrics, Harvard Medical School, will be held on February 20, 1936, at 8 15 P M at the Boston Lying in Hospital.

Dr Judson Smith will review papers on the treatment of habitual and threatened miscarriages together with recent work on the physiology of corpus luteum.

The pathological aspects of miscarriages and abortions will also be presented.

Professor Hisaw of the Harvard University will discuss the work on the physiology of the corpus luteum.

ARTHUR T HERTIG, M D, *Chairman*

MEDICAL CLINIC AND STAFF ROUNDS AT THE PETER BENT BRIGHAM HOSPITAL

At 3 30 P M on Thursday, February 20, in the Amphitheatre of the Peter Bent Brigham Hospital, Dr Henry A Christian, Physician in Chief, Hersey Professor of the Theory and Practice of Physic in the Harvard Medical School, will give a medical clinic. To it are cordially invited practitioners and medical students.

REMOVAL

WARREN D RUSTON, M D, announces the removal of his office to 29 Commonwealth Avenue, Boston.

NOTICES OF MEETINGS

HARVARD MEDICAL SOCIETY

The next meeting of the Harvard Medical Society will be held in the Peter Bent Brigham Hospital Amphitheatre (Shattuck Street Entrance), Tuesday evening, February 25, at 8 15 P M.

PROGRAM

- Presentation of Cases
Spontaneous Hypoglycemia By Dr Russell M Wilder, Mayo Clinic, Rochester, Minnesota
Medical students and physicians are cordially invited to attend.

MARSHALL N FULTON, M D, *Secretary*

NEW ENGLAND HEART ASSOCIATION

The next meeting of the New England Heart Association will be held at the Memorial Hospital, Worcester, Mass (Knowles Hall, Nurses' Home), Monday, February 24, 1936, at 8 00 P M.

PROGRAM

- 1 Effects of Contagious and Infectious Diseases on the Heart
A General Statement of Main Topic Dr O H Stansfield
B Late Results of Contagious and Infectious Diseases on the Heart Dr E H Haloran
- 2 Acute Benign Pericarditis Dr F B Carr
- 3 Coronary Symptoms in Pernicious Anemia Dr J J Dumphy

All members of the New England Heart Association and interested physicians are invited to attend.
JAMES M FAULKNER, M D, *Secretary*

NEW ENGLAND OPHTHALMOLOGICAL SOCIETY

The 308th meeting of the New England Ophthalmological Society will be held on Tuesday, February 18, at the Massachusetts Eye and Ear Infirmary, 243 Charles Street, Boston.

9 00 A.M.—Clinic and Operating Room
11 30 A.M.—Neuro-Ophthalmological Conference.
Applicant for Membership

8 00 P.M.

Simple Technique for Plotting Diplopia Dr. William D. Rowland.

Paper

History of Ophthalmology as a Specialty in New England. Dr. Allen Greenwood

MASSACHUSETTS MEMORIAL HOSPITALS

There will be a meeting of the Surgical Section in the Ladies Aid Room, Talbot Memorial, 8. East Concord Street, Boston on Friday February 14 at 12 noon.

Papers will be presented by Dr. Charles Sziklas and Dr. David B. Stearns

MILTON C. GREEN, M.D., Secretary

NEW ENGLAND PHYSIOLOGICAL THERAPY SOCIETY

The regular meeting of the New England Physical Therapy Society will be held at the Hotel Kenmore Boston on Wednesday evening February 19 at 8 o'clock

PROGRAM

Elementary Physics of Galvanism. L. L. Campbell, Ph.D., Professor of Physics Emeritus Simmons College

Clinical Uses of the Galvanic Current

Iontophoresis. Gynecological Conditions. Frederick H. Morse M.D. Pioneer in Electrotherapy Nerve Conditions. H. Houston Merritt, M.D., Associate in Neurology Harvard Medical School. Some Common Conditions in General Practice. Claude L. Paysant, M.D., Chief, Department of Physical Therapy Quincy Hospital.

The Council will meet at 6 P.M.

Members and guests will meet for dinner at 6 30 in the Empire Room at the Kenmore.

All members of the medical profession are cordially invited to attend.

WILLIAM D. McFEE, M.D., Secretary

41 Bay State Road Boston.

A JOINT MEETING TO DISCUSS A COMMUNITY PLAN FOR MEDICAL CARE

The Boston Council of Social Agencies the Boston Health League and the Hospital Council of Boston have issued invitations to a meeting in Sprague Hall Boston Medical Library 8 Fenway on Monday February 17 at four o'clock.

Ross Garrett, Co-Ordinator for the Medical Eco-

nomic Security Council in operation in Washington D. C. will explain the plan which includes hospital insurance maintains a Service Bureau to assist in the payment of professional fees attempts to determine the ability of the patient to pay and regulates the distribution of the burden of free care among all hospitals

Since this plan, which is sponsored by the Council of Social Agencies in Washington is being watched with great interest in other parts of the country we are fortunate in having this opportunity of discussing it with Mr. Garrett. It is hoped that staff and board members of organizations interested in this subject will be present.

Mr. Garrett's visit is made possible through the cooperation of the Massachusetts Medical Society the Massachusetts Dental Society and the Hospital Council of Boston.

This Problem Concerns Everyone.

THE NEW YORK HARVEY SOCIETY

The fifth lecture of the Harvey Society will be given at the New York Academy of Medicine on February 20 by Dr. John F. Fulton, Sterling Professor of Physiology Yale University School of Medicine on The Interrelation of Cerebrum and Cerebellum in the Regulation of Somatic and Automatic Functions.—Science.

SOCIETY MEETINGS, CONGRESSES AND CONFERENCES

CALENDAR OF BOSTON DISTRICT FOR THE WEEK BEGINNING MONDAY FEBRUARY 17 1936

Monday February 17—

4 P.M. Joint Meeting to Discuss a Community Plan for Medical Care. Boston Medical Library 8 Fenway, Boston

8 15 P.M. Boston Medical History Club at the Boston Medical Library 8 Fenway, Boston

Tuesday February 18—

9 10 A.M. Boston Dispensary 25 Bennet Street Boston. X-Ray Demonstration Dr. Alice Katin

9 A.M. 11 30 A.M. and 8 P.M. New England Ophthalmological Society Massachusetts Eye and Ear Infirmary 143 Charles Street, Boston.

12 M. South End Medical Club Office of the Boston Tuberculosis Association 551 Columbus Avenue Boston.

2 30 P.M. Pediatric Ward Visit. Massachusetts Eye and Ear Infirmary

Wednesday February 19—

9 10 A.M. Boston Dispensary 25 Bennet Street, Boston Auscultation of the Abdomen Dr. Neil Stevens.

11 12 M. Clinic-Pathological Conference. Children's Hospital

8 P.M. New England Physical Therapy Society Hotel Kenmore Boston.

Thursday February 20—

8 30 9 30 A.M. Clinic, Surgical Staff of the Peter Bent Brigham Hospital, at the Peter Bent Brigham Hospital.

9 10 A.M. Boston Dispensary 25 Bennet Street Boston. Heart Clinic. Dr. Samuel H. Proger

3 30 P.M. Medical Clinic at the Peter Bent Brigham Hospital.

Friday February 21—

9 10 A.M. Boston Dispensary 25 Bennet Street Boston. Some Aspects of Clinical Endocrinology (With Motion Pictures). Dr. Lewis M. Hurxthal.

Sunday February 22—

4 P.M. Free Public Lecture Harvard Medical School, Building D Longwood Avenue. The Role of the White Blood Cells in Health and Disease Dr. Henry Jackson Jr.

Open to the medical profession.

BOOK REVIEW

The Sexual Relations of Mankind Paolo Mantegazza. 335 pp New York Eugenics Publishing Company \$6 00

Singularly modern in its point of view is this translation of Mantegazza's *Gli amori degli uomini*, first published in 1885 Mantegazza was a physician, laboratory worker, traveler and anthropologist, this compendium of the love-customs of the tribes and races of the world reflects the mental attributes of a man educated as he was At the same time he was an Italian, and as he himself tells us (p 290) "As I see it (and I trust no one will take offense at this), the Italians are the foremost lovers among civilized races"

The book consists of a great collection of facts regarding various phases of the sexual side of life, including the Festivals of Puberty, The Sexual Embrace and Its Forms, Mutilation of the Genitals, Sexual Choice, Position of the Woman in Marriage, Monogamy, Polygamy and Polyandry and so forth The customs of many outlandish tribes, some of whom the author himself had visited, are presented in a scientific manner, free from sensationalism It has become one of the source-books for this sort of information The presentation of these facts is often accompanied by Mantegazza's comment, at the end of the book he submits a list of what he considers to be the first signs of a better future for love These points, written fifty years ago, might well be taken from the present day writings of one of our most free thinking writers They are as follows

"Less ignorance of sexual matters on the part of young girls

"Free choice on the part of both sexes, in place of a contract imposed by parents and endured by their offspring

"Less hypocrisy

"Restitution of its dignity to marriage, divorce being surrounded by wise precautions

"And finally—and do not be scandalized by this—a sincere and clean-cut separation of free and sexual love from that troth which is plighted between two creatures, who have come to know each other thoroughly well over a period of time, and who are animated by a desire to found a family"

ENDOMETRIOSIS*

With Particular Reference To Conservative Treatment

By RICHARD B. CATTELL, M.D.,† AND NEIL W. SWINTON, M.D.†

ENDOMETRIOSIS is a relatively frequent finding of the pathologist at autopsy and during the examination of the surgically removed uterus and adnexa. In spite of the clinical interest in this subject since Sampson's original work, a preoperative diagnosis is rarely made, its presence may not be recognized at the time of operation, and the end results of radical and conservative treatment are too little known. While there have been many reports in the literature since Sampson's¹ "articles of 1921", most of the discussions on this subject have been concerned with the origin and mode of transmission of this lesion and few papers have appeared dealing with the end results following surgical treatment. Only by the addition of further groups of cases to the literature can a true appreciation of the importance and clinical nature of endometriosis be obtained. Certainly there is every evidence that the lesion is much more common than was previously suspected. We wish to present a brief résumé of the literature and to report forty three cases observed at the Lahey Clinic together with the end results of treatment.

Endometriosis is an abnormal growth of endometrial tissue in an alien location. This term was adopted by Sampson to avoid the confusion of terms which had been used in the literature. The terms adenomyoma, adenomyosis, chocolate cyst, hemorrhagic perforating cyst, menstruating cyst, and others have since been abandoned as misleading or incomplete. The use of the term endometriosis implies, as Graves² suggests, an acceptance of Sampson's theories of etiology. The tumor manifestations of this disease are expressed by the word endometrioma, first mentioned by Blair Bell³ in 1922.

Von Rokitsky⁴ in 1860 described adenomyoma as a pathological entity for the first time. Between 1893 and 1896 von Recklinghausen⁵ published a series of articles ascribing the origin of these tumors to the development of rests in the Wolffian ducts. Cullen⁶, in 1896, made the first mention of an adenomyoma of the round ligament and since that time he has added considerable knowledge to the general sub-

ject. Russell, in 1899, first described endometrial tissue in the ovary. Pick⁷, in 1905, described four cases of what he called "adenoma endometrioides ovarii" and his description of endometrial tissue in the ovary has not been improved upon. He believed that the extra uterine growth arose from Gartner's ducts and the paracophoron. Blair Bell³, Fletcher, Shaw⁸, and Donald⁹ presented early reports from England while Norris, Casler, Schwarz¹⁰, and Cullen⁶ reported early cases in this country. Previous to 1921, when Sampson made his original report covering twenty three cases less than twenty instances can be found in the literature. Janney¹¹ reported a series of observations made previous to the publication of Sampson's work but these were published later. Meyer first published his serosal theory in 1919. He believed that the germinal epithelium of the surface of the ovary retains its embryonal stage potentialities of growth and may differentiate into endometrial like tissues. Novak¹² accepted this explanation and believed that dissemination through the peritoneal cavity arises from that point. It has been the observation of several writers that the colomic epithelium creates endometrial like tissue by a process of metaplasia and Sampson, in later publications, does not deny this possibility. Sampson¹, however, was the first to advance the theory that the endometrial like tissue found in ovarian substance was not a metaplastic change from embryonic remains but represented true endometrial tissue which had been regurgitated through the fallopian tubes in the menstrual blood and become implanted in the ovaries. While it is true that Sampson's theories may not account for all the endometrial like tissue in the abdomen and pelvis, his theories have not been disproved, and we feel that when true aberrant endometrial tissue is encountered, its presence can be explained by his theory. For a more complete résumé of the literature one should refer to the excellent discussion by Graves¹³.

It has been difficult to determine the incidence of endometriosis. Sampson had reported 188 cases up to 1929. While doing 296 pelvic operations he found the lesion sixty four times or in approximately 22 per cent. In the same year Smith¹⁴ reported 159 cases observed at the Free

From the Lahey Clinic, Boston, Mass.
†Catell, Richard B.—Surgeon, Lahey Clinic, New England Deaconess and New England Baptist Hospitals. Swinton, Neil W.—Surgeon, Lahey Clinic. For records and addresses of authors see This Week's in us, page 331.

Hospital for Women while Keene and Kimbrough²¹ in 1930 reported 118 cases. In the past five years we encountered the lesion in forty-three patients during which time over 400 hysterectomies were done. From these observations endometriosis must be considered a relatively common lesion.

The age incidence of endometriosis closely parallels the age incidence of menstruation. The youngest patient in our series was twenty-two years, while the oldest was sixty-two years, the

FIGURE 1 Ovarian endometriosis.
Mrs. C. K. aged thirty-three married for six years with no pregnancies. Five years previously suspension and appendectomy had been performed. At operation there were dense adhesions in the pelvis with multiple chocolate cysts involving both tubes and ovaries. She had been well four years since operation.

average age incidence was 37.1 years. Smith⁵⁵ reports an age variation of twenty-three to seventy-two years with the majority occurring between thirty and fifty years. Keene and Kimbrough²¹ report age limits of twenty-two to sixty years with only two beyond the menopause. In an early series of forty-nine cases Sampson^{39, 49} found four cases under thirty (8 per cent) but in our series ten or (23 per cent) were under thirty years of age. Twenty-seven of our patients were married and sixteen were single. Of the married group, fifteen had borne an average of 3.2 children. In the remaining twelve, one had been married but two months, another had had one miscarriage in three years of married life, and ten had not had children. This gives a sterility index of forty per cent. Nine of these sterile cases had ovarian endometriosis, while one had a rectovaginal lesion. Smith's⁵⁵ sterility index was 20.6 per cent and Keene and Kimbrough²¹ found 40.9 per cent sterile.

Cases have now been reported showing endometriomata in all pelvic organs and in many

other localities. The ovary is the most common site, and in our series twenty-six cases showed ovarian implants, 40 per cent of these being bilateral. Graves¹³ reports a bilateral involvement of the ovaries in 30 per cent. The uterus is the next most common site, nine of our cases showed lesions in the wall of or on the surface of this organ. Rectovaginal endometriosis is less common but in the presence of bowel obstruction it is important to differentiate this condition and carcinoma of the rectum. There were four patients in this group, two of whom had bowel obstruction. We believe that all obstructive lesions in the rectum must be considered malignant until proved otherwise. However, with no history of bleeding or mucus in the stools and with a normal appearance of the mucosa at the site of the obstruction on proctoscopic examination, one must suspect that the lesion may be endometriosis. The round ligament, intestinal wall, fallopian tube, abdominal sac, appendix, and the peritoneum were the sites of the lesion in our other cases. Endometriomata have been reported also in the groin, bladder, umbilicus, omentum, vulva, perineum and vagina.

The duration of symptoms in our series varied from thirty-six hours to ten years. Acquired dysmenorrhea, pelvic and lower abdom-

FIGURE 2 Adenomyoma of the uterus.
Miss E. P. aged thirty-five, had had menorrhagia for three months. Pelvic examination showed moderate irregular and nodular enlargement of the uterus. This illustration shows the distribution of the adenomyoma in the uterine wall.

mal pain, abnormal menstruation, backache, leucorrhea and lower abdominal tumor, named in the order of frequency, were the principal complaints in our group. Keene and Kimbrough²¹ add to this group bladder or rectal pain, associated with menstruation, as being a frequent symptom. They point out that the abnormal bleeding may be due to the associated

lesions which are frequently found. We feel that this fact should be kept in mind in considering most of the complaints of these patients who have endometriosis. Other symptoms are associated with lesions in particular localities. As already mentioned, the recto-vaginal group is particularly important, because symptoms of intestinal obstruction may occur. Graves¹² and Sampson¹³ and more recently Meigs¹⁴ have reported interesting cases of this nature. Ovarian endometriosis may simulate salpingitis or appendicitis. Lesions of the round ligaments usually present tumors near the external ring which show tenderness and swelling at the time of menstruation. Endometriomata may appear as tender nodules in the groin, or perineum or vulva. Bladder endometriosis may be mistaken for malignancy. Keene¹⁵ in 1925 reported the first case of this nature. Some of the most interesting cases of endometriosis have been transplants in abdominal wounds. These lesions are usually soft, dark-colored tumors which become engorged and painful at the time of menstruation, or there may be actually menstruating sinuses. Meigs¹⁶ case four in his 1930 series was most interesting. It presented a menstruating sinus which had apparently been caused by the transplantation of endometrial tissue during ventral fixation of the uterus. Endome-

A preoperative diagnosis of endometriosis is seldom made. Three such cases were recognized before operation in our series and several more had this tentative diagnosis, one was an obvious lesion of the round ligament while the other two caused obstruction of the sigmoid at the time of menstruation. Smith¹⁷ in his series of 159 cases reports that endometriosis was considered in about twenty instances. Shirer¹⁸ made no preoperative diagnosis in thirty patients observed. Ovarian endometriosis will always be difficult to differentiate from chronic pelvic in-

FIGURE 4. Endometriosis of the round ligament. Mrs. B. W., aged thirty nine had one pregnancy during nineteen years of married life. A lump had been noted in the right groin for nine years changing in size during menstruation. Low power magnification.

FIGURE 3. Adenomyoma. High power magnification of the same case as figure

trial tissues in the appendix may cause symptoms suggestive of appendicitis. Outerbridge¹⁹ in 1917 and 1925 reported cases of this nature.

Physical examination of these patients is usually not characteristic in most cases. However if the lesion is in the umbilicus, round ligament, perineum or abdominal scar the findings may be quite obvious when the symptoms are associated with menstruation.

flammation. Graves¹² states that when the posterior cul-de-sac and rectal wall are involved there is a peculiar, pinched, nontender, induration which an experienced examiner can at times differentiate from a posterior parametritis. We feel that with an increasing realization of the frequency of endometriosis and with a better knowledge of its clinical manifestations the condition will more often be suspected previous to operation. Such symptoms as abnormal menstruation, sterility, acquired dysmenorrhea, and lower abdominal pain should make one consider endometriosis particularly when associated with a fibroid uterus and malpositions of the uterus.

There is a very high incidence of associated lesions with endometriosis. Some observers have thought that an enlarged uterus may be instrumental in producing the backwash of menstrual blood through the tubes. Adhesions and abnormal positions of the fundus were most common in our series, occurring in seventy per cent of the cases. Fibroid uterus was next common,

occurring in forty-nine per cent. Much less commonly were found chronic salpingitis (diagnosed microscopically) twenty per cent, and simple ovarian cysts, fifteen per cent. Two cases of fibrosarcoma of the ovary were found in our series although they had no association with endometrial tissue. We did have, however, one case of bilateral ovarian endometriosis with an adenocarcinoma arising from the endometrial tissue. Sampson found endometrial tissue in seven of sixteen cases of carcinoma of the ovary. Smith⁵⁵ found malignancy in seven per cent of his cases of endometriosis and believes that these implants may undergo malignant degeneration.

The pathology of endometriosis varies somewhat with the locality involved, but the lesion

FIGURE 5 Higher power magnification of endometrioma of round ligament

itself is usually quite characteristic. In the ovary the so-called "chocolate cyst" is typical. These vary from small spots on the surface of the ovary to quite sizable cysts of fifteen to twenty centimeters in diameter. In 30 to 50 per cent of the cases, the cysts are bilateral. They may lie on the surface of the ovary or deep in its substance and may be multiple in the same ovary. They may take up the entire structure of the ovary. The cysts are lined with a low cuboidal epithelium and are surrounded with stroma resembling that of endometrium of the uterus with similar glands and tubules. This tissue undergoes the same changes as occur in the endometrium of the uterus during menstruation. There is a discharge of blood and desquamated cells into the cavity of the cyst, similar to that into the cavity of the uterus. Here, however, there is no outlet for the blood, and it may be retained in the cavity of the cyst or may rupture through the capsule into

the abdominal cavity. The retention of blood in these cysts gives the characteristic chocolate or tarry content. The discharged blood creates a reaction in the surrounding peritoneum which is responsible for the multiple, firm, tenacious, adhesions so commonly found associated in the pelvis in these cases. Further endometriomata may be found in these adhesions themselves, or may be spread in this manner to other structures. At times, the entire pelvis will be found to consist of one conglomerate mass of firm adhesions and endometriomata. Graves¹³ mentions the frequency, with which, in these cases of extensive adhesions, the tubes are free from involvement, and this agrees with our experience. He feels that this is an important differential point from inflammatory lesions of the pelvis. Although twenty per cent of our patients showed chronic salpingitis on microscopical study, we did not feel that the tubes in the majority of the cases were abnormal at the time of operation.

When we consider our cases of "Chocolate Cysts", that did not show endometrial tissue on section, we are faced with several possibilities. Endometrial tissue may have been present and not found, but as we review the literature and find that most every observer has had similar experiences, we do not believe that this is so in all instances. Some may be corpus luteal cysts with hemorrhage. Some may be occlusions from the germinal epithelium and due to the influence of the ovarian hormone, undergo endometrial-like changes. They may be simple cyst adenomata of the ovaries with hemorrhage. MacCarty²⁷ emphasizes the black or tarry appearance of the latter, rather than the chocolate-colored content of the endometrial cyst. There seems to be no doubt that all hemorrhagic cysts of the ovaries are not necessarily endometrial in origin. This fact should be remembered when treatment is being considered.

Adenomyomata of the body of the uterus closely resemble ordinary fibroids. They, however, are not definitely circumscribed and cannot be easily shelled out of their surrounding structures. They are usually found near the uterine horns or on the posterior wall of the fundus, but they may be in any position where ordinary fibroids occur. They are made up of coarse, fibrillary fibromyomatous tissue which merge with the uterine wall. Within are glandular elements which may become filled with blood and many resemble chocolate cysts. They are usually small and seldom are they recognized at operation.

Rectovaginal endometriosis is usually first noted as a smooth hard lesion just behind the cervix. As it grows, it gradually involves the anterior rectal wall and may go on to the stage of obstruction. The lesion may involve the vagina early in its course and the diagnosis can be established by biopsy.

The treatment of endometriosis depends on the location and the extent of the lesion, the age, and general physical condition of the patient. Complete involvement of the ovaries and the necessity for castration have been rare in our experience. Three of our patients have had children following the removal of one ovary for endometriosis. Of four patients treated conservatively by Wharton², three subsequently bore children. Keene and Kimbrough found that twenty-eight per cent of their patients treated conservatively later had normal pregnancies. The removal of all ovarian tissue in young women is a very serious matter and we do not feel that it is warranted in this disease where local excision can be performed. In women over forty years of age supravaginal hysterectomy with removal of tubes and ovaries is indicated. In poor risk patients, it is to be remembered that castration will cause the lesion to recede and usually relieve symptoms. In this group, the production of an artificial menopause through the use of Roentgen therapy should be considered.

In the rectovaginal group, where intestinal obstruction has not occurred, the disease can be relieved by local excision followed by the production of an artificial menopause. Where intestinal obstruction has occurred the obstruction must first be relieved by colostomy. This colostomy should be done in such a manner that it can later be closed, since following the removal of the ovaries the lesion will regress and the obstruction will be relieved.

In bladder endometriosis, the production of an artificial menopause will cause the lesion to disappear. In endometrial tissue of the appendix, the removal of that organ will remove all trouble. Local excision will usually cure other types of endometriosis.

In the accompanying table, we have record

seventeen cases treated radically was 41.5 years. The average age of the conservative group was 29.2 years. The average follow up in both groups was approximately 25 years. In our group, treated by bilateral removal of the ovaries, all were cured. In the conservative group, two of our patients were improved, while the remainder were relieved. One patient still has nodules at the apex of the vagina, and has occasional lower abdominal pain. She prefers this situation, to castration, since she plans marriage. Another patient has had a biopsy of a small rectovaginal lesion and is now receiving Roentgen therapy. There were no cases in either group unimproved and there was no operative mortality.

SUMMARY

A series of forty three cases of endometriosis are reported together with a brief résumé of the literature. The incidence, location and symptomatology are presented.

A preoperative diagnosis of endometriosis is seldom made but the lesion should be suspected in the presence of abnormal menstruation, sterility, acquired dysmenorrhea and abnormal pelvic findings. The lesion is much more frequently recognized than formerly.

We wish to emphasize the importance of conservative treatment of endometriosis during the active child bearing period. Three patients in this series having ovarian endometriosis following removal of one ovary subsequently had children.

The end results after both conservative and radical treatment are satisfactory in properly selected cases.

HUTCHINSON-BOECK'S DISEASE (GENERALIZED "SARCOIDOSIS")*

Historical Note and Report of a Case With Apparent Cure

BY FRANCIS T HUNTER, M D †

"Names are good servants but bad masters"
(Jonathan Hutchinson)

IN presenting the following communication the author has two objects, that of clarifying a minor point of medical history, and that of again drawing the attention of the practitioner to a rare but most interesting pathologic entity. In its history this malady not only reveals the scant attention often paid by investi-

gators to prior observations in the literature, but illustrates the disadvantages of multiple designations for a single disease and of a too rigid specialism in medicine, the latter is exemplified by the fact that after Caesar Boeck's paper (which gave the name to the disease) thirty-five years elapsed before any concerted attempt was made to correlate the known data on this morbid condition. That the patient whose case history is to be presented regained his normal health, though of no little interest, is possibly of less importance than that he suffered from an affection observed for the first time sixty years

*From the Medical Department of the Massachusetts General Hospital, Boston Mass

ago by Hutchinson, reported as involving the internal organs twenty years ago, by Kuznitzky and Bittorf, and whose protean manifestations are even now scarcely recognized.

As a number of investigators (such as Boeck, Besnier, Tenneson, and Hutchinson) have been eponymically associated with the condition commonly called "sarcoïd", it seemed possible that a careful re-reading of the early papers on the subject might bring to light new facts of historical interest. This conjecture proved to be correct. In the course of the inquiry it soon became obvious that Jonathan Hutchinson, four teen years before Besnier and twenty four years before Boeck, had specifically called the attention of practitioners and dermatologists to the skin manifestations of the malady. His name, to most physicians, connotes only the characteristic teeth seen in congenital syphilis, but, his unflagging curiosity, his keen powers of observation, and his passion for intelligent note-taking stimulated him to write voluminously on many other subjects. "His *Archives of Surgery* (1889-1899) consisted of ten volumes,* issued in periodic form, the entire contents written by himself, forming a great storehouse of original observations on disease, which will some day be studied like the works of John Hunter." Accordingly, a certain amount of attention will be devoted to him and to his relations with Caesar Boeck in order that the reasons for believing him to be the first to describe "sarcoïd" may be made clear. Those authors who later drew attention to the involvement of the internal organs by the same pathologic process will be considered very briefly, since several reviews of the literature accompanied by adequate bibliographies have already appeared in print.

HISTORICAL

Jonathan Hutchinson, as early as 1869 observed a patient with peculiar purplish, raised lesions on the front of the legs, on the fingers, and on one forearm, which were irregular in size and shape, possessed sharp margins and smooth surfaces, and were neither tender nor painful. Associated with this there was brawny edematous swelling of one finger. In his *Illustrations of Clinical Surgery* (1875) Hutchinson¹ described the case in detail, published a chromolithograph of the patient's hand and after a year's observation remarked that medicine of various sorts had had no effect on the lesions. He further stated "During a visit to Christiania in the summer of 1869 Dr Bidentkap was kind enough to show me the collection of pathological drawings in the University Museum, and amongst these was one taken from a patient of Professor Boeck, showing a pre-

cisely similar condition of things to that delineated in my portrait. The only particulars that I could ascertain were that it was from the hand of a Swedish sailor, who appeared to be in good health, and who was not known to have suffered from gout. Professor Boeck told me that it was the only example of its kind that he had ever seen."

When one recalls that this "skin" affection has been honorifically termed "Boeck's Disease", the above statement at first glance suggests that Caesar Boeck knew of Hutchinson's early case and deliberately failed to mention it when he wrote his own paper twenty four years later. But if one pays due regard to the dates and to the ages of the individuals concerned, this cannot be true. The Professor Boeck mentioned here by Hutchinson must have been Carl William Boeck (1808-1875), an acknowledged authority on syphilis and Caesar Boeck's² uncle.

Moreover, in 1889, ten years before Caesar Boeck's important contribution, Besnier³ described a lesion of the skin to which he gave the name *lupus pernio* ("chilblain lupus"). Although acknowledging that his case was similar to the one delineated by Hutchinson (1875), he thought the two were not completely identical. He portrayed, however, involvement of the nose and face, and noted for the second time what he termed "*synovites fungueuses*" of the fingers. In 1892 Tenneson⁴ reported a similar case, but added nothing essentially new to the description of the disease except that the lobes of the ears might be affected. Three years after Tenneson's paper Besnier published his *Musé de la Hôpital Saint Louis* and included in it colored lithographic reproductions of the lesions of the nose and fingers, these plates, however, did not materially improve upon Hutchinson's lithograph of twenty years before.

In the meanwhile, the Dr Bidentkap mentioned above had succeeded Professor William Boeck in the professorial chair at Christiania and had in turn, been followed by Caesar Boeck. It was, therefore, as a professor that the younger Boeck, in 1899, described for the first time⁵ the morbid histology of the skin. His paper was published first in Norway and, with minor changes, a few weeks later in this country. In regard to the earlier reports in the literature he remarked "The only clinical description known to me which bears any resemblance to my case is given in a recent paper by Jonathan Hutchinson in his *Archives of Surgery*, October 1898." I dare not say that the skin affection there described as "Mortimer's Malady" is identical with my case since the latter shows some very marked clinical features not found in Mortimer's disease, and since Mr

The series is from 1889 to 1900 and consisted of eleven issues the last of which was not completed and sent to the subscribers until 1910.

Hutchinson frequently called new syndromes or diseases by the name of the patient—in this case Mortimer—although other and more scientific names might be devised, it is perhaps doubtful whether they would be more convenient."

Hutchinson has had no opportunity to examine his cases histologically. Nevertheless, I am inclined to believe that they are only variant types of the same group of diseases and perhaps, later on, may be found to represent benign forms of so-called pseudoleukemic affections of the skin." We must assume, therefore, that Boeck did not regard the cases reported by Besnier and Tenneson as similar to his own.

One might wonder, at this point, why Hutchinson had not investigated more thoroughly these two patients with "Mortimer's Malady", for he had presented one of them to the Dermatological Society of London about 1894. In respect to this, however, he writes "The general opinion was, I believe, that the disease was sarcoma, and it was strongly urged that portions should be removed for microscopic examination. This was subsequently suggested to the patient, and with the result that I did not see her again for two years."⁹ This statement, apparently, explains his "lack of opportunity to examine his cases histologically." It is probable that he did not dare suggest a biopsy to the second patient.

It now appears that Hutchinson not only enjoyed the friendship of Professor William Boeck but was acquainted as well with the nephew Caesar, for he, Hutchinson, was president of the Dermatological Congress of London in 1896.¹¹ At this meeting Caesar Boeck, as vice-president for Norway, presided over one of the sections, and at the gala banquet responded to a toast. Doubtless, too, Boeck attended the garden party at Haslemere* given to the members of the Congress by Hutchinson and his daughter. So when, in 1898, Hutchinson¹² referred to a recent visit of his "esteemed friend, Professor Boeck of Christiania", obviously from the date, the latter could have been none other than Caesar Boeck, since the uncle had died in 1875. From this one might assume that the younger Boeck knew of Hutchinson's visit in 1869 to his uncle and of their discussion of their similar cases. But since there is no suggestion in Hutchinson's writings that he considered his own case of 1875 as one of either "Mortimer's Malady"^{9, 13} or of "Mabey's Malady",^{14, 15} the likelihood that Caesar Boeck was entirely unacquainted with it,—the first to be reported in the literature,—seems most probable.

The next important contributions came from the roentgenologists. As early as 1902 Kienbock¹⁴ noted on x-ray examination curious "cysts" in the digits and toes of a twenty-seven year old patient who had acquired syphilis five years previously, but in those early days of roentgenology he attributed the findings to lues

Kreibich¹⁵ in 1904 definitely associated these roentgenologic lesions with *lupus pernio*, but, in ignorance of this, Remijnse¹⁶ in 1907 reported a case of "dactylitis syphilitica" accompanied by generalized lymphadenopathy in a patient who gave no definite evidence of congenital or acquired lues and who showed no lesions on the skin. The excellent skiagrams of the osseous changes which he reproduced in his paper would now be considered quite characteristic of "sarcoid." In a paper published in 1910 Rieder¹⁷ re-described the roentgenologic appearance of the phalanges in two of his patients, and again observed that each one had active *lupus pernio*. Thus a decade passed with no important contributions other than descriptions of the bony lesions.

Five more years elapsed before involvement of the internal organs was noted. In 1915, Kuznitzky and Bittoif¹⁸ reported a case of skin "sarcoid" with evidence of morbid changes in certain of the viscera. A biopsy of the skin showed the histologic pathology previously pictured by Boeck, but in addition, the patient exhibited lymphadenopathy and splenomegaly, the blood examination revealed a leukopenia and eosinophilia, and mottled infiltration of the lungs with some enlargement of the hilar glands was demonstrated by the x-ray. Schaumann¹⁹, in 1917, in describing the microscopic appearance of the lymph glands and later²⁰ of the osseous lesions, identified *lupus pernio* and Boeck's sarcoid as one and the same disease. Finally Jüngling²¹ (1919) not only again described the "cystic" appearance of the phalanges seen on x-ray examination, but biopsied the soft tissues of one finger, found the characteristic microscopic changes described by Boeck, and gave to the bony deformations demonstrated by the x-ray the term "ostitis tuberculosa multiplex cystica".

Scattered papers depicting either the clinical or histological changes in the lymph glands or internal organs began to appear in print during the next ten years. Rischin²², Bernstein²³, Goeckerman^{24, 25}, Bernstein, Konzlemann and Sidhek²⁶, Doub and Menagh²⁷ all contributed pertinent observations. Between 1931 and 1934 other cases with visceral involvement were recorded by Kiklin and Morton²⁸, Funk²⁹, Bayer³⁰, Bergel and Scharff³¹ and Sannicandro³². In 1932 an important monograph was published by Kissmeyer³³ which summarized the previous contributions to our knowledge of the disease and included many original observations of his own. In May of 1934, the *Réunion Dermatologique de Strasbourg*³⁴ devoted itself entirely to the consideration of "sarcoid." This symposium brought out a number of unique aspects of the malady, papers being contributed by dermatologists, internists, pathologists and roentgenologists from Germany, Switzerland, France, Sweden and Denmark. At this meeting

*For a delightful description of Hutchinson's country home see the article by William Osler. Phila. Med. Jour. 41: 463-455 1899. (This is a hitherto uncatalogued letter by Osler.)

**Mabey was another patient of Hutchinson.

Kissmeyer acquiesced to the suggestion that the name he had bestowed upon the condition be changed from "La maladie de Boeck" to "La maladie Besnier Boeck". From the historical evidence here presented, however, I believe the malady should properly be called "Hutchinson Boeck's disease" or "Hutchinson Boeck's Sarcoid".

HUTCHINSON BOECK'S "SARCOID"

The second and chief purpose of this paper is to draw again the attention of the medical profession to the protean manifestations of this bizarre condition. Neither, strictly speaking, a disease of the skin nor related to sarcoma, practically always benign in its course, its etiology has to date remained undetermined. Although thought by some to be a manifestation of tuberculosis, in the majority of cases the tuberculin test and the usual animal inoculations of this sue have given negative results, but those who believe in tuberculosis as the cause of the disease explain these negative tests by assuming that the histologic changes are a result of "anergy" to the chemical products of the tubercle bacillus. Because a similar microscopic pathology is at times seen in leprosy, syphilis, and in certain instances after subcutaneous injection of oil or paraffin, some authors, particularly the French school, speak of a "terram sarcoïdique". Finally, Kissmeyer and his followers refuse to accept tuberculosis as the etiologic factor, and, although offering in confirmation nothing but negative evidence regard the disease as due to an unknown organism or virus and therefore entitled to be considered an entity *sui generis*.

In the field of *pathologic histology*, very little has been added to Boeck's original description—foci of endothelial cells with a thin margin of lymphocytes and connective tissue septa, no tendency to necrosis, caseation, or accumulation of Langerhans' giant cells,—an appearance somewhat similar to that seen in tuberculosis. This histologic picture has been recorded not only in the skin, but in the lymph glands, spleen, lungs²², bones, mucous membranes, conjunctivae, and parotid gland.

Treatment has usually consisted either of local therapy such as fulguration of the skin lesions, or of general measures such as arsphenamine intravenously or Fowler's solution *per os*, but due to a tendency of the affection to spontaneous remissions, the efficacy of these procedures has been difficult to evaluate. Recently Lomholt²⁴ has reported good results in twelve cases from injections of "antileprol", but he has not as yet followed his patients over a sufficiently long period of time to confirm this impression. In the present instance the patient was induced to give up exercise, to go to bed

in the afternoon and early in the evening, to get as much sunshine on the bare skin as possible, and take large amounts of cod liver oil and extra amounts of milk. The results of this régime, over four and a half years' time, were impressive.

CASE REPORT

The case is that of a white male married, American high school teacher aged thirty six, who entered the hospital May 19 1931 complaining of weakness and loss of weight of one year's duration.

Present Illness Four years ago he noted a superficial lesion on the chin and some time thereafter similar lesions appeared on the face, trunk, and upper extremities. During the next three years the patient tried several different remedies and an equal number of doctors without amelioration of his condition. One year ago he appeared in the Dermatologic Clinic and at that time showed several firm olastic, dull red, pea-sized nodules on the chin and about the corners of the mouth. Fowler's solution was prescribed, but there was only slight improvement. A lesion on the left shoulder was biopsied and a pathologic diagnosis of "sarcoid" was made. Several of the skin lesions were fulgurated with a high frequency current with some cosmetic improvement.

For the past year his strength had been falling and he had declined from 193 to 142 pounds in weight. Three or four months prior to entry an additional symptom, consisting of a slight cough accompanied by occasional nausea and vomiting on arising in the morning made its appearance. At or about the same time he began to note gaseous eructations and epigastric distress at various times during the day apparently unrelated to meals. Eight weeks before entry he was examined in the Medical Clinic because there had been no improvement in his skin condition and because pathology in the chest had been observed on fluoroscopic examination. A roentgenogram revealed large lobulated shadows at the lung roots and he was consequently referred to the Tumor Clinic as a case of probable lymphohistioma.

The family and marital histories gave no significant information.

Past History He had never had an important infectious disease. In the U S Infantry during the World War he had received severe shrapnel wounds which involved the left frontal region of the skull the posterior aspect of the left shoulder and the soft tissues of the left upper arm and for these had undergone numerous operations. During the past thirteen years since the war he had experienced two generalized convulsions lasting a few minutes each which he attributed to temporary digestive disturbances. Aside from frequent attacks of sinusitis and slight dyspnea on exertion the rest of the past history was negative.

Physical examination showed a well-developed and nourished man, with some weight loss. There were numerous 0.5 to 1 cm. slightly umbilicated dull purplish red non tender shiny nodular lesions with small surrounding areas of induration scattered over the face, trunk arms and upper legs, and which seemed to show a predilection for the old shrapnel scars. There was a large flat, atrophic scar over the posterior aspect of the left shoulder the result of an old burn and a linear scar on the mesial aspect of the left upper arm the result of an operation for a gunshot wound. On the skull there was a circular bony defect (3 x 2.5 cm.) in the left frontal region with visible pulsation synchronous with the radial pulse and which bled on cough

ing There were several 1 cm glands under the angles of each jaw and a similar sized one below the symphysis of the mandible there were two 4 cm rather soft, nontender, slightly matted glands in each axilla and in each groin, a 1 cm gland could be palpated in the right posterior cervical triangle. The lungs showed no abnormalities to percussion and auscultation. On examination of the abdomen the tip of the spleen was easily palpable 2 to 3 cm below the costal margin on deep inspiration, and on deep pressure there was slight tenderness in the right upper quadrant and epigastrium. The liver edge was not felt.

Laboratory findings Urinalysis was negative. Blood examination showed white blood corpuscles 9,800, red blood corpuscles 4,650,000, hemoglobin 80 per cent. The blood smear showed polymorpho-

FIG 1 Microscopic section of axillary gland removed for pathological examination. Note collections of epithelioid cells without giant cells or caseation

nuclears 65 per cent, small lymphocytes 14 per cent, mononuclears 20 per cent, eosinophils 1 per cent, platelets slightly increased, the red blood corpuscles normal in appearance. The Hinton test was negative. An intradermal tuberculin test was moderately positive. During the patient's stay in the hospital the temperature varied from 97.5° to 100.5°.

A biopsy of the lymph nodes in the axilla was performed and, at the same time, a skin lesion on the left forearm was removed for examination. **Pathological report** (Dr T B Mallory) The specimen consists of two enlarged lymph nodes, the larger measuring 1 x 2.5 x 4 cm. They are moderately firm and on section have moist, glistening, pinkish white finely lobulated surfaces. There is a small elliptical piece of skin measuring 1.5 x 1 cm. On microscopic examination the lymphoid tissue is largely replaced by well defined compact conglomerate tubercles showing little caseation. The section from the forearm shows the typical structure of the lesion which is usually called sarcoid.

X-ray examination (Dr G W Holmes), April 27, 1931 (three weeks before entering the hospital) "No organic pathology in the stomach or duodenum. The diaphragm is sharply outlined on both sides and moves normally with respiration. There is rather soft, fine mottling at both lung roots. The changes are most marked around the root of the lung and gradually fade out toward the periphery. On the right side there is a narrow dense band extending across the chest in the region of the septum between the upper and middle lobes. There are large lobulated shadows at both lung roots. These shadows occupy the region of the hilus of the lung. They are quite dense and are about 8 cm long and 5 cm wide. They are roughly kidney shaped. There is no evidence of calcification. The heart shadow is large and prominent in the region of the right auricle. There is no increase in the supracardiac shadow. The aortic knob is indistinct. There is no erosion of the ribs or other abnormality of the chest wall. There is no evidence of enlargement of the peritracheal glands. The examination shows evidence of an extensive process involving both lung fields, the interlobar septum on the right and the hilus regions. It is accompanied by some dilatation of the heart. Lymphoblastoma is the most probable diagnosis." (See fig 2)* "The x-ray films of the hands show no deviation from the normal."

FIG 2 X-ray film of the chest May 15 1931 (See text)

Progress Notes June 15, 1931 On a modified tubercular régime (consisting of rest in the afternoon, cod liver oil, extra milk, etc.) there had been a gain of three pounds in weight and the glands seemed to be smaller.

August 3, 1931 The patient had gained eight pounds since discharge from the hospital. There were no new skin nodules. Several of the newly developed lesions had disappeared. The older lesions were healing well, a few having disappeared entirely. There was a 2 cm. gland in the right axilla, two 2½ cm glands in the left axilla, three or four 2 to 3 cm glands in the groin, and the spleen was palpable 1 to 2 cm below the costal margin.

*The reproduced x ray film was taken three weeks after the foregoing report was made but on comparison the two were almost identical in appearance.

September 11 1931 The patient was still gaining weight, having added twelve and a half pounds since leaving the hospital. His general health was excellent. The lesions which had been fulgurated were gradually fading and no new ones had appeared. The glands in the axilla measured about 2 cm. those in the groin had not changed in size. The spleen was just barely palpable on deep inspiration.

August 12 1932 Since the last examination a year ago the patient had been unusually well. He had gained steadily in weight up to 179 pounds. All the skin lesions had completely disappeared and had not recurred. On physical examination scars of the fulgurated skin lesions and a 2 cm. gland in each axilla were the only objective findings. The spleen could not be felt.

September 15 1933 For the past year the patient had enjoyed the best health since 1917. His weight had varied between 185 and 190 pounds. He felt physically more ambitious than he had for years, and seemed normal in every way. On careful questioning no symptoms of any sort could be elicited and no new lesions could be detected on physical examination. In the right axilla there was still present a 1 cm. superficial nodule, but no glands of importance could be felt in the axilla or groin, and the spleen was not palpable on deep inspiration. X-ray examination. "There is a definite and striking improvement in the appearance of the chest since the last examination. The lung roots now ever are still definitely abnormal. The millary and linear shadows in the lung fields have almost disappeared (Fig. 2).

FIG. 2. X ray of the chest, September 1, 1934 (Forty months after treatment was begun.)

September 24, 1934 Aside from occasional heart burn the patient's condition had remained excellent. Physical examination was entirely negative. X-ray examination. The gastro-intestinal tract showed no variations from the normal. The chest exhibited the identical appearance described the previous year.

October 31 1935 There was no evidence of disease on physical examination. X-ray films of the chest revealed no detectable differences when compared with those made in September 1933.

COMMENT

The evidence from the cases previously reported in the literature and from the one presented here is that "Hutchinson Boeck's 'sarcoid'" is a generalized systemic disease. It affects at times not only the skin, but the lymph glands,—both peripheral and those at the hilus of the lungs,—the spleen the parenchyma of the lungs, the phalanges of the fingers and toes, the mucous membranes, the conjunctivae and the parotid gland. In its power of invading many organs it simulates lymphoblastoma and is therefore a disease which should be recognized and studied by the internist, the surgeon, and the roentgenologist. Since iritis is not infrequently reported as a precursor or as accompanying the skin lesions, the ophthalmologist, too, should be acquainted with it. One of the probable reasons it has remained so long overlooked by the internist is the multiple and philologically formidable nomenclature given it by dermatologists and others—Boeck's disease, Besnier's disease, Besnier Boeck's disease, Besnier-Tennesson's disease, benign lymphogranulomatosis, sarcoid, multiple benign sarcoid of the skin, ostitis tuberculosa multiplex cystica, milary (or disseminated) lupoid, *lupus pernio*, and "chilblain lupus." It would simplify matters if all concerned would agree upon a single cognomen at no distant date.

The case I have reported showed changes limited to the skin and reticuloendothelial system—lymph nodes and spleen, for although Kiss Meyer doubts the involvement of the spleen in many of the reported cases, the fact that under treatment this patient showed a decrease of the splenic enlargement which paralleled the regression of the lymphadenopathy, cannot, in my judgment, be dismissed as fortuitous. It seems logical, therefore to assume that the spleen would have shown the same morbid histology as that demonstrated in the biopsied lymph gland.

This malady, finally, offers a possible solution to another problem,—that of the true diagnosis in instances where apparently healthy patients without skin lesions, give evidence of increased hilus shadows accompanied by diffuse infiltration of the lungs at x-ray examination—an appearance not infrequently reported by roentgenologists as tuberculosis. Are these patients suffering from *Hutchinson Boeck's "sarcoid"*? More careful roentgenologic and clinical observation may in the future throw light on this question.

CONCLUSIONS

(1) Hutchinson Boeck's Disease (generalized "Sarcoidosis") is a generalized systemic disease and may involve in addition to the skin,

the lymph glands, spleen, lungs, bones, mucous membranes, conjunctivae, and parotid gland

(2) Jonathan Hutchinson was presumably the first to mention the condition and deserves to be remembered as long as the disease is eponymically designated

(3) A case is reported with involvement of the skin, lymph glands (peripheral and hilar), and spleen,—with apparent cure after four and a half years' observation

CATHARTIC TO MIX IN BREAD COSTS FOOD
FAKERS \$600 FINE

A powerful coal tar cathartic has no proper place in bread or any other product sold as a food. The Food and Drug Administration regarded phenolphthalein as an adulterant when it was used as an ingredient of what the manufacturer called a "laxative health bread." The Federal court at St. Louis, Mo., agreed with the food officials and imposed a \$600 fine on Edward Ownen, Frank Dawdy and Glenn Allmon trading under the fancy name of Bakers' Research Co.

This concern has been selling "Ownen's Vlti-Veg" a mixture of flour, bran and between ten per cent and twelve per cent of phenolphthalein, a coal tar cathartic. This mixture was recommended to bakers for addition to their regular bread mix. The product was to be marketed as "laxative health bread."

Bread, a staple article of the diet and consumed by everyone from infancy to old age, should not be used to mask the presence of a powerful laxative. In the opinion of the Food and Drug Administration W G Campbell, Chief of the Administration,

remarked recently, "It is peculiarly appropriate that the deliberate perpetrators of this, one of the most flagrant types of adulteration uncovered in recent months, should receive one of the largest recent penalties — \$600." Shipments totaling some 700 packages of "Vlti Veg" were seized and destroyed last June—*Bulletin, U S Department of Agriculture*

CONNECTICUT MEDICAL AFFAIRS

THE TRI CITY MEDICAL SOCIETY

The February meeting of the Tri City Medical Society of Norwich, New London and Willimantic, Conn., was held Thursday evening, February 6, 1936, at Uncas-on-Thames, Norwich, Conn., with the President of the Norwich Medical Society, Dr John Raymer, presiding.

Dr William B Castle of Boston, Associate Professor of Medicine at Harvard University, delivered an informal talk on "Recent Advances in Blood Diseases." In his talk Dr Castle reviewed some of the recent theories regarding polycythemia, pernicious anemia, leukemia, etc., and answered questions relative to these blood diseases.

NEW ENGLAND SURGICAL SOCIETY

FOOT STATICS AND SURGERY*

BY FREDERICK J. COTTON, M.D.†

FOOT statics have been neglected of late years and apparently little understood.

Yet the foot is the weight-carrier that keeps us off the ground, and its smooth function unimpaired by ill use, repaired or reinstated in case of ill use, deformity or injury, is most important.

Up to 1900, foot statics was considered a problem in purely static, not kinetic, mechanics.

A vast literature had been produced, German in the main, enlightening, if my memory serves me, in works by one Meyer.

Out of all this survives one item only. There is a sort of "triangle of support" (seen here) and, if the stress of body weight transmitted through the leg, falls outside, or more often in

FIGURE 1

side of this neat triangle, trouble is likely to follow for the line of weight-bearing through the tibia should not be far off centre for normal function (Fig 1).

Forget all the rest!

Particularly, forget all you ever heard about "arches", both longitudinal and transverse. If one must be architectural about it there are trusses in the foot, *not arches*, and the truss conception is best forgotten also, it isn't so simple as that!

Dr Edward H. Bradford first had the idea of the moving tarsus, I think and of muscle balance and of the value of muscle training which is so important to a proper conception of foot function.

Whitman, with his rocking plate, and Dane with his "pronated foot", understood much about all this as well.

Lovett and the writer worked a season on the kinetic mechanics of the foot using the then new x ray on the living foot to help.

Then, Dr Thomas Dwight, the anatomist, went over all our work and changed his teach-

ing. The specimens relevant to all this are still in the Warren Museum!*

Some people digested all this to their profit, and that of their patients but since then nothing especial has been added to our knowledge until one Mr Philip Wiles Loudon surgeon neatly described what we had been stupid enough to overlook, namely the muscle function of the long peroneal in relation to the mobile function of the first toe unit. We had all known the effects of displacement of this unit but no one had worked out the corrective function of the peroneus longus muscle! Perhaps, one may now talk with confidence (with reserves, of course) of the function of bones, joints and muscles, and of their action in the amazing supporting weight function of the foot.

At any rate, I am going to try to make this intelligible.

*Read at the Annual Meeting of the New England Surgical Society at Manchester N. H., September 3, 1925.

†Cotton, Frederick J.—Consultant, Boston City Hospital. For record and address of author see "This Week's Issue" p. 33.

The foot has many joints The body weight, transmitted through the tibia and astragalus, drops to the os calcis, scaphoid, and cuboid These three form a queer irregular cup, into which the astragalus fits (Fig 2)

FIGURE 3
Calcis rocks in and out (lat. view)

FIGURE 4
Same from behind.

In this cup, the astragalus *rocks* (or more accurately the cup rocks under it) in standing and walking

The calcis rocks *in* and *out*, and, as the heel goes inward, the whole heel bone rotates *under the astragalus* (Figs 3, 4 and 5) And, with

this rock and shift, the “cup” being of uneven diameter, the scaphoid moves *inward*, and the whole front part of the foot goes inward as well

And this movement occurs in just the same way, whether the foot moves in inward rotation about a vertical axis, or the leg, and with it the astragalus, rotates outward (Fig 6)

FIGURE 5
Upper drawing shows relaxed ‘pronated’ position Below is shown the correction to proper position by muscle action—in proper balance

Apart from this motion, but working in like direction, there is *some ad- and ab-*duction movement (with slight rotation) at the *mediotarsal* joint (Fig 7)

And then, too, there is the important independent action of the first member, comprising the first cuneiform, the first metatarsal and the great toe, moving up and down on the scaphoid as a base (Fig 8)

With the downward movement of this “first member”, under control of muscle pull of the long peroneal, the “anterior arch” arches up

The tibialis posticus lifts and accents the “long arch”, and the long flexors, particularly of the hallux, help in this lifting

FIGURE 4.

The tibialis anticus helps not at all, but does lift the foot to clear the toes in stepping. It is, properly, as Wiles tells us, an *opponent* of the long peroneal, tending to flatten both arches in the position of *inversion* of the foot. It does not act to put the foot into stable position, but

FIGURE 1

into a varus far out of any normal standing position. All the exercises based on action of the tibialis anticus are not only useless but harmful.

The long peroneal pulls the cuneiform and metatarsal, the "first" member, down and out

FIGURE 5

Movement down and out of 1st cuneiform, and 1st metatarsal under pull of peroneus longus.

FIGURE 6

The metatarsals seen from behind. Pulled by the long peroneal, metatarsal I flexes downward, rotates and moves outward.

Unaided by the posterior tibial it would roll the foot into undesired valgus. (Fig 9)

Its real function is to bring the head of the first metatarsal *into the tread*, and to raise the so-called "anterior arch" as the posterior tibial and the flexors deepen the "long" bring about a varus position

The tibialis posticus can be *ex-* toned up, easily. Such exercise t
ors as well. (Fig 10)

The long peroneal can be brought back to efficiency only by restoration of voluntary function, as far as we know, a matter of education which is not always easy (Fig 11)

Many have long known that plates are but a crutch for old ladies, they cure nothing, and prolong treatment

Modified shoes and heels help those who will help themselves, and they stall the very young along to an age where these children can be induced to cooperate, mainly on the plea of possible efficiency in sports, or dancing. The minimum age for normally vain females is four to

FIGURE 10

Exercise to develop and tighten the muscle group of tibialis posticus long toe flexors et al that make for supination and the lifting of the arch

five, males about two years behind this schedule

Such exercises as will bring back real coordination of the tibialis posticus, flexors, and long peroneals require an attention and persistence not commonly met with in our offices, as the patients run, day in, day out. Yet cure of the familiar type of flat foot depends in the end on restoring muscle balance and proper action

For this reason the problem is arduous. Many of our patients are going to stick to plates or "supporting" shoes, till they sit down permanently in chairs, or accept steel leg braces

The vigorous, young or old, can be cured by temporary support, reinforced by directed exercise, in the great majority of cases

Some flat feet, not a few, can be helped by operation, thereby changing statics. Not many are these likely to be cured, unless care is at hand to utilize muscle action made easier by the operative correction

The helpful operations seem to be the following

The Gleich Operation This is applicable to many conditions usually the result of injury (fig 12) whether to tarsus or ankle. It has the advantage that the heel may be shifted in any desired

FIGURE 11

The thumb action in the foot. Above one sees weight carried on the outer side of the foot by muscle control—the first metatarsal is entirely out of weight bearing function

Below one sees the first metatarsal down in action. This is what has been called the thumb action in the foot. It is the result of the down driving action of that curiously aligned muscle the peroneus longus that goes down the leg across under the foot just to do this—to pull the first metatarsal and its toe down out into the working tread of the foot.

direction and for some distance. Also it is a strangely undisturbing operation. It was devised two generations back for the cure of the flat foot of bony type, the "Rad-Fuss" so common in peasants. It was forgotten, revived here to correct bad results in os calcis fracture—since used for many purposes

The Cotton Advancement Operation This consists in advancement of the calcaneo-scapoid ligament, a logical operation which is useful in certain few cases

Operation on the first member, the cuneiform wedge

This is applicable to any type of case in which, from long standing deformity the first metatarsal head cannot be made to carry any weight. Such a condition may result from an inveterate flat foot dating back to childhood with changes in bone shape as well as lax ligaments. Or it may be the result of trauma with some deformity.

In hallux valgus cases such an ascent of the "first member" is common and important.

In some cases of "anterior arch" trouble, one finds it in marked degree and it seems likely

FIGURE 11

Clutch operation. Diagram

This operation, devised a generation or more ago, to treat most of the flat feet of European peasants, has proved of the greatest value. One can shift the heel in or out at pleasure. Revived here for handling certain cases of valgus following a calcaneal fracture, the operation has proved of value for all sorts of things—for example, shifting a heel in a case of club foot, brought back, except for this detail by previous handling. It is simply an osteotomy across the neck of the calcaneus that makes it possible to shift the heel down and forward—see A, A', A'' or inward—see C-C' or what one will.

that in cases of such trouble we should describe the deformity as an ascent of the first member rather than as a descent of the second, third or fourth.

In any of these classes a bringing down of the metatarsal head for three fourths of an inch is simple and more can be obtained.

The operation is simple not painful, and weight bearing begins within a month.

In the short series of cases done since I devised this operation there has been no trouble in any and the correction obtained has in no case been lost.

It seems to merit further use.

There are other static factors, first the short heel cord.

Short heel cord means "metatarsal strain,"

from the resultant habitual "toeing out" that infallibly drops the long arch, and makes trouble.

Often, but not always, this results from habitual wearing of high heels.

It has long been a source of income by way of tenotomy of the tendo-achillis. (Fig 14)

This operation, at times justifiable, may usually be avoided by the simple use of the "shoe" or strap wrench, devised by the late Dr Gwilym Davis, the use of which does not even need anesthesia.

FIGURE 12

If the first metatarsal is up it may be brought down, as here shown by splitting the first cuneiform bone and wedging the resulting gap wide open. This is a matter of surgical carpentry; the amazing thing is the prompt repair and the early return of function.

Another factor of disability is the "dropping of the anterior arch," sometimes associated with the distressing "Morton's toe" from nerve pinching, usually between third and fourth metatarsals.

Proper pads, set in behind the tread of the ball of the foot, with or without circular strapping, relieve most of these cases, temporarily and may be required permanently although persistent exercise of the flexors of the toes will usually effect a real cure if persisted in.

In certain obstinate cases with or without hallux valgus, the operation already described does the work and is far preferable to any resection of metatarsal heads. (See figure 13)

Hallux valgus is very much a matter of statics.

Blamable to short shoes not always and rather often running in family lines, it cripples often

because of "bunion" friction, but also because there is usually an *ascent* of the first metatarsal, a sort of separation of the first from the rest, "primo-varus" which means nothing but a description of the deformity from adduction of this metatarsal with a wide space between this and the next metatarsal

With this, an upward movement of the first member takes place, and it was on this type of hallux valgus case that I first did the opera-

FIGURE 14

Lengthening of the tendo-achillis. An operation to be done seldom. As a rule the Gwilym Davis strap-wrench does the work. But if one must cut the tendon the matter comes down to a question of judgment as to length. Of course the section is to be oblique

tion here talked about. In these cases the bony wedge taken out of the hallux valgus makes a good wedge to keep open the gap in the osteotomy gap in the first cuneiform

Operations on hallux valgus, as such, we cannot consider here because of restricted space for they are many, but the operation for dropping the first metatarsal to its proper level with the others just shown is of importance (Figs 15, 16, and 17)

"Hallux rigidus", which is loss of dorsal flexion between the first metatarsal and its phalanx, from arthritis or due to fixation in plaster, is crippling because it hurts, and because this hurt makes the patient "toe out"

FIGURE 15

(X-ray before and after Jenner)

Mrs J

A very vigorous heavy-weight of forty five years crippled for years. The obvious usury of the metatarsal heads is aside from the present point. The working disability was of the first unit. One sees left the original set up right the postoperative detail

FIGURE 16

(X-ray before and after Jenner)

Same seen laterally. To the right one sees the reshaped metatarsal head shifted downward. Also a superfluous chip of the graft at the point where the cuneiform was wedged apart.

FIGURE 17

(Photo after Jenner)

Same case. The two feet, right foot operated. Later the left foot was operated on in the same way. The clinical result unbelievably good, considering the damaged heads of the other metatarsals about which we did nothing

and roll the foot into valgus, and so puts it out of commission, mechanically

Such a condition again is readily remediable by easy surgery

And that means only a clearance of the top half of the first metatarsal joint surface, not a difficult, but useful procedure.

In relation to statics fracture cases must be considered.

Fractures of the metatarsals are problems of correction by local osteotomies when indicated.

Metatarsal displacements not rarely call for correction by removal of a deep, often wide, wedge from the convex side.

The typical if not common, varus deformity accompanying fracture dislocation of the scaphoid can be corrected with a Gleich operation.

Faulty statics following os calcis fracture may call for removal of bone on the outer side with or without a shifting of the heel. Such removal of bone with the Gleich operation works out very well.

The correction by arthrodesis has the drawback that it deliberately destroys all movements of the tarsus which might otherwise be preserved.

It has its place for relief of pain, not for any correction of statics.

Deformity from astragalus injury usually means arthrodesis between the tibia and astragalus with such sloping of cut surfaces as will give right statics.

This does not sacrifice any tarsal motion. As trapelectomy is to be avoided. The results are sometimes tolerable but the patient is at best a lumping cripple.

Now as to ankle fractures proper. Outward deviation of the foot with valgus means Pott's fracture. Given any considerable deviation (see fig 1), any relief short of operation is apt to be partial, if not futile. Long ago Stimson showed us how. This is his bimalleolar osteotomy (fig 18), a most useful operation.

FIGURE 18

Stimson's bimalleolar osteotomy.

A cross-cut and a lateral shift inward. The first, I think, of all the operations of reconstructive surgery as good as what Stimson described it, a generation or more ago.

For backward dislocation my class III fracture sometimes labeled with my name, there are two procedures.

Often enough the end result shows a backward displacement with no elements of a stable joint, and only too often with an obliquity of the remains of the joint inward or outward.

For such a case there is nothing for it but a radical reconstruction, such as is shown in figure 19A, this is usually practicable, though a

FIGURE 19

In a Class III fracture. If the foot is back, entirely out of alignment, one must reconstruct. The posterior fragment cannot be moved. The malleoli can be cut across a fresh bed cut in the tibia for the astragalus.

These operations do rather well and they do not result in ankylosis. Given one joint surface covered with cartilage, one gets no cross adhesions. Loss of motion may often result but not from cross adhesions between joint surfaces.

difficult and heavy operation. I have done it often. Lately in one case, that of an elderly woman, this seemed impractical due to the risk of time shock. An arthrodesis with correction was done.

In other cases of this class the displacement is less and there is some sort of a decent joint

with the disability largely from contact of astragalus and front edge of the tibia or pinching of tissue between

In such a case the simpler operation shown in figure 19B suffices, and usually gives great relief out of proportion to the simple nature of the operation

Static problems of varus deformity are uncommon When met with they must be handled

FIGURE 20

Supramalleolar osteotomy
Subperiosteal resection

Class IV fracture

Given the not unlikely adverse result one may

- (1) Shorten the fibula relatively too long and correct any serious deviation of the tibia by a cross cut osteotomy or
- (2) do a subperiosteal resection of the superfluous part of the fibula or (3) do an arthrodesis. Gallie's technique is the best

by shifting the foot back (in reversed Pott's) by bimalleolar osteotomy, or by doing a transverse or wedge osteotomy of both bones rather close to the ankle joint. If the incisions are sloped down from outside and inside to the center, correction may be made very exactly and without danger of slipping

The reverse deformity may be dealt with in

the same way, and so may anterior or posterior bowing, and this applies to many cases with displacement due to fracture well above the joint. From all points of view and especially with regard to speed of repair the low osteotomy is to be preferred

In cases of my "class IV", smashes of the lower end of the tibia with comminuted fractures into the joint with almost inevitable deformity and with some shortening almost inevitable, incurred in heavy falls on the foot with the foot driven upward, smashing the tibia, driven upward past and away from a fibula which may often enough not be broken at all, one has real problems in statics

Varus deformity with forward or backward spreading is what one sees in late results in the unlucky cases, and the unfortunate ones are lamentably many

Shortening cannot be corrected but often a low osteotomy of both bones will at least give proper weight-bearing (Fig 20A, B)

Some cases may be fit only for arthrodesis with static correction, giving at least a mobile tarsus and foot, in others the problem is simpler. It is the long fibula, often intact, driven down into the os calcis, throwing the foot into sharp varus position and giving pressure pain besides

In such, a subperiosteal resection of the fibula (fig 20C) is all that is to be done, and the results are surprisingly good as a rule

Limits imposed on time and space make this a brief talk around the pictures and all detail as to manipulations, apparatus to ease strain, shoes and modifications of shoes, and the large field of exercise work brought down to working terms, must be omitted

Perhaps I have enabled you to have a clear picture of what we know of foot statics, of the importance of keeping this clear view with us in much of our surgical work

DISCUSSION

DR. EZRA A JONES (Manchester, N H) I am very much interested in this subject and it deserves much better discussion than I am able to give to it. As a matter of fact, the title of this paper did not tell me very much of what it was about. The first time I saw Dr Cotton's paper was last night. I determined to go home and read it over and write a better discussion, but I was unable to do so

However, the points that he brings out are very interesting and, I think, very valuable. The infantile cases I think, have shown us a lot about muscular action of the foot, although I was not ac-

qualified with the fact that the peroneus longus was so valuable but I think it probably is.

I think the exercises that we give our patients to correct their flat feet, when they come up on the toes, improve the tone of the peroneus longus and probably help pull the first metatarsal head down.

There is another point that Dr Cotton brought out that is interesting to me showing that the rotation or eversion of the foot is principally at the astragalocalcaneus joint. I remember trying to cure cases of infantile, attempting to give them a better weight-bearing position by ankylosing the astragalus and scaphoid, without very much result. But when Dr Hoke devised his operation which not only ankyloses the astragalus and scaphoid but also the astragalus and calcaneus it gave I think, better results.

The pronation is probably what causes us pain. You all know that the American Negro has perfectly flat feet and he does not have very much foot trouble. He has the same degree of flatness in the white race is usually accompanied with pronation. The amount of pain they have depends more on the pronation than on the flatness of the long arch.

I think Dr Cotton was right when he said we should disregard our arches and talk about our weight-bearing. Of course in weight-bearing where the line comes on the inner side of the foot instead of the outer side, we get all kinds of troubles and trouble as you all know is not limited to the foot itself, but causes rotation of the knee joint, backache and gives us many disabilities.

I was interested in the Gleich operation. I should think it would be an excellent operation for our cases of fractures of the os calcis where the bone is displaced outward that is where it is rotated outward. As you know there is a large amount of callus formation usually under the external malleolus. In chiseling that off we do not get very satisfactory results. I am wondering if this Gleich operation would not help to bring the calcaneus back where it should be.

I was interested in Dr Philip Wilson's operation of ankylosing the astragalus and the calcaneus but it seems to me that this would give you better weight-bearing without destroying any joint surface. Thank you.

PRESIDENT JOHNSON Is there any further discussion?

Dr. DAVID CHEEVER (Boston, Mass.) *Mr. President*—I was immensely interested in Dr Cotton's paper and especially in his beautiful drawings.

I just wanted to ask him to elaborate a little further about the statement which I understood him to make that there are no arches as such in the foot. Of course, I think all of us have been brought up with the architectural conception of an teroposterior and transverse arches. That is pretty well fixed in our consciousness and Dr Cotton himself is still arch-conscious in his description as he said he would be because in the description of his demonstrations his pictures he frequently mentioned the word arches.

If you recall figure 7 I think it was which showed in coronal section the transverse arch through the bases of the metatarsals it seemed to me it was a beautiful picture of an arch as I understand an arch with a tie-beam growing across underneath represented by the tendon of the peroneus longus.

If they are not arches I would like to get a little clearer idea of why they are not, as in the occasional anatomical talks that I have to give I can be a little more up to date.

PRESIDENT JOHNSON Is there any further discussion? If not, perhaps Dr Cotton will conclude.

Dr. COTTON As to Dr Cheever's arches, it is perhaps a matter of words. Strictly speaking architecturally an arch is a curve which has abutments at the hips and may be built with a keystone or as a simple arch which maintains its height on account of the balance of the down thrust of the weight of the arch and whatever load is put on it, the counterbalance of that against the resistance of the hips at the side.

In the foot we have nothing of that sort. We have what is analogous to a roof in a house. We do not have Gothic or Roman cathedrals with arches. We live in houses that are tied together with trusses. A roof gets very little thrust, ought to give no thrust at all on a great beam. It is fastened together with cross-ties, king post, queen post and is tied together as one structure. That is what we get in the foot. There is no thrust against the immovable lateral end to take weight, but we do have this truss which is tied together with a strap below.

It is not very accurately described that way but there is something of an arch in it. In the long arch we have a plantar fascia running fore and aft which is the lowest strap of the truss and we have the ligaments lying under the tarsal bones close under the tarsal bones as an accessory strap.

It is perfectly true the astragalus comes down exactly like a keystone but I think it is just as well not to bother too much about that because as I will say in a minute the whole thing is complicated by a lot of other factors.

As far as the transverse arch is concerned that is nearer an arch. The posterior transverse arch under the arch of the foot that is held in this position by ligaments, again acting as straps across the base of this almost semicircular truss. The anterior arch I do not think can be called an arch at all. The arch is held up by the action of the flexor muscles. If you ever handle those cases and try to cure anterior arch dropping so-called, by educating the muscles, you find you can do it in the majority of cases very easily.

I had a personal experience of that a couple of years ago when I happened to be the victim of an accident. During my convalescence one anterior arch after the other went. I was completely crippled. I did not do anything about it except to put a pad in for a day or two and exercise my toes. The arches came up all right.

The muscles, and not even the ligamental structures, hold the anterior arch and I do not think there is any anterior arch—transverse yes longitudinal yes perhaps. If you want to call a truss an arch that is a matter of words.

The reason why I dislike to think of arches or even trusses is because these motions of the foot, which interest us are largely rotary motions, controlled by the most complicated curves in the joints of the foot. If you settle down to work out the anatomy of the astragalus and the cup in which it rotates, it is enough to confuse you. You can see it happen but even with the articulated bones especially articulated in your hand it is hard to see what happens.

What happens is that the front part of the foot is thrown in a given direction on account of the fact that the astragalus goes out and wedges the scaphoid in. It is that complicated kind of thing that makes it possible for us to walk and not the support of anything like an architectural arch.

I would like to say a word in closing about the Gleich operation. This history is rather curious. I have not been able in research again to find the reference to that years ago in getting together

the Bradford and Lovett book, I did a vast amount of German reading. I ran into the Gleich operation. Later when I began to take up os calcis fractures I revived it for just the class of os calcis cases.

I did the Gleich operation. I have used it whenever I felt like it for all kinds of deformities of the foot where I wanted to shift the heel. Whenever I wanted to shift the heel, I shifted it there. The operation is a very simple one if you have ability to calculate angles. All you do is cut across the neck of the os calcis. Then you take your hand or

hammer, whatever you like, and put the heel where you want it.

The os calcis has an enormous amount of repair power, as you know, too much in many instances, and these cases are able to bear weight without any distortion of the fragment, as early as five weeks. There is no reaction to the operation or sense of pain in any case I have ever seen. I must have done it a good many scores of times.

I recommend to you, gentlemen, the Gleich operation.

THE EFFECT OF CORAMINE ON POSTPARTUM PATIENTS UNDER THE ANALGESIC INFLUENCE OF SOME BARBITURIC ACID DRUGS*

BY ALEXANDER A. LEVI, M.D.,† AND CHARLES M. KRINSKY, M.D.†

MANY successful attempts have been made in obstetrics to alleviate the pain of childbirth. In addition to the amnesia and analgesia desired, some postpartum reactions which occur occasionally are found objectionable. Among these are the duration of the narcosis long beyond the period of pain and many hours past the end of the third stage of labor, the urinary retention, and the possibility of an idiosyncrasy to the specific medication used. These undesirable complications are largely responsible for the objections to analgesic agents in obstetrics. We have, therefore, endeavored to determine what medicament could perhaps decrease the period of postpartum narcosis and thereby eliminate a great many secondary manifestations. Coramine was used, in our series, because of favorable reports by investigators¹ on the efficacy of this drug in diminishing the duration of narcosis. The reports did not concern the use of this drug in obstetrical patients. We therefore undertook the study of this problem.

INVESTIGATION

It has been the accepted procedure for many years at the Evangeline Booth Hospital to administer nembutal by mouth and paraldehyde in oil by rectum for the purpose of obtaining obstetrical analgesia. The dosage varies from four and a half to six grains of nembutal given by mouth and four to six drams of paraldehyde in three ounces of olive oil administered by rectum, depending upon several variables such as parity, weight and progress of labor. These are given under as uniform conditions as possible. The criteria are first, regular pains which occur about five minutes apart, secondly, engagement of the presenting part, and thirdly, two or three fingers' dilation of the cervix. From study of many records the individual susceptibility to

this medication cannot be definitely evaluated or anticipated, but it can be stated that the patients in the majority of instances enjoyed excellent amnesia. We were also able to conclude that the most undesirable effects were the length of postpartum narcosis beyond the time of actual need, the development of urinary retention, and the lassitude which persisted for several days. Practically no difficulty was encountered with the babies.

Idiosyncrasies of one form or another to drugs are well known. Our experience in such a case, and the recovery of the patient after treatment with coramine suggested the possibility of minimizing the undesirable reactions of nembutal and paraldehyde by its administration. The results obtained in this case proved to be the impetus for our study. In brief, the patient, a hospital case, was a primipara, aged twenty-one, who had been carefully observed throughout her labor. The prenatal history was normal. Ten and one-half grains of nembutal by mouth and nine drams of paraldehyde by rectum were given in small, divided doses over a period of fifty-four hours, the medication being repeated as consciousness returned. The baby weighed 7 lbs and 6 ounces and was delivered by a low forceps application and episiotomy. With the exception of a marked caput, the baby appeared and remained normal, breathing well after the delivery. The maternal pulse averaged 88 and the fetal heart 140 per minute until four hours before the delivery, at which time both increased, to 144 and 172 respectively. At the time of the delivery, the blood pressure was systolic 98 and diastolic 78. Soon after delivery, the maternal pulse increased from 128 to 140 per minute, and the blood pressure dropped to systolic 76 and diastolic 60. The fundus was firm, and very slight oozing from the vagina was noted. There were no evidences of abnormal bleeding from the uterus, cervix, or vaginal mucous membrane. The patient presented a clinical picture indicative of marked respiratory embarrassment and

vasomotor collapse seemingly due to the drug administration. Her face appeared pinched and drawn. Her lips were cyanotic and the heart sounds were rapid but regular. Respiratory excursions were shallow and barely perceptible. The pulse was thin and of poor quality. The fingernails were cyanotic and the extremities were cold and clammy. When seen in consultation by one of us (A. A. L.) it seemed that death was imminent.

The patient was treated for shock by means of intravenous glucose and saline therapy, elevation of the foot of the bed, heaters and blankets, and coffee was administered by rectum. In spite of these and other heroic measures, the response was poor. The symptoms and blood pressure—systolic 76 and diastolic 60—remained the same. It was then deemed advisable to attempt respiratory stimulation by the inhalation of a carbon dioxide mixture. The patient showed little reaction even to this apparently because of the shallow inhalations. Three cc. of coramine was then administered intravenously and intramuscularly. Within three quarters of an hour from the time this medication was given, the patient became conscious. She was able to converse with the attendants. Her respiration improved. The cyanosis slowly disappeared, and the blood pressure rose from 76 systolic and 60 diastolic, to 108 and 74 respectively. Following this experience the patient made an uneventful recovery, appearing quite normal twelve hours later. The puerperium was without event.

A medical consultation was obtained during the course of the treatment. The opinion coincided with that of the obstetrical consultant that the reaction was perhaps due to the drugs administered, probably those of the barbituric acid group.

The group studied consisted of forty consecutively admitted patients who had received nembutal and paraldehyde in the routine manner. This was divided into one group of twenty patients who were given coramine and a second group of twenty patients who served as a control. The two groups were comparable as far as age, parity, race, and color were concerned. Five cc. of coramine was given intramuscularly after the third stage of delivery had been completed. The average patient had in the mean time reacted from the mild ether anesthesia which was administered. The blood pressure, pulse, and respiratory readings were taken at this time and repeated every fifteen minutes for the first hour and twice during the second hour. The depth of ether anesthesia and narcosis, the degree of amnesia, and the extent of motor activity were noted. The time from the end of the third stage to consciousness was charted in each case.

RESULTS

Significant differences were obtained between the two groups when the average time of recovery of consciousness was computed. It was seven hours and forty eight minutes for the control group and five hours and forty five minutes for the coramine group. The average dosage of nembutal and paraldehyde administered was practically identical being 4.4 grains of nembutal and 5.1 drams of paraldehyde for the control group and 4.7 grains and 4.5 drams respectively, for the coramine group (Table 1).

TABLE 1

Patients	Cases	Nem bu tal	Par alde hyde	Time
Controls	20	4.4	5.1	7 Hrs 47 Min
Coramine study	20	4.7	4.5	5 " 45 "

The consensus of those closest (i.e., nurses and attendants) to the patients was that fewer catheterizations were necessary for the coramine treated group. This may be attributed, perhaps, to the decreased time of postpartum narcosis.

A study of the pulse, respiration, and blood pressure revealed that the type of response to coramine is a matter of uncertainty. In twenty five per cent of the cases the pulse, respiration, and blood pressure were raised. In an additional twenty five per cent they were slightly lowered, while in fifty per cent they remained unchanged. Whether this latter seventy five per cent would have shown a negative or positive response with additional coramine is problematical. No other noteworthy observation was made which could be ascribed to the use of coramine.

SUMMARY

- 1—A study of the applicability of coramine in decreasing the time of postpartum narcosis was made.
- 2—One-half of the group of forty mothers received five cc. of coramine intramuscularly after the third stage. The remaining twenty patients were used as controls.
- 3—The length of narcotization after the third stage was decreased from an average time of seven hours and forty eight minutes to five hours and forty five minutes in the coramine group.
- 4—A patient "in extremis" after administration of nembutal and paraldehyde recovered after treatment with coramine.
- 5—The effect of coramine on respiration, pulse, and blood pressure in our series was variable.
- 6—Coramine is no doubt of value as a respiratory stimulant when the respiration is so depressed that the patient cannot "breathe in" carbon dioxide oxygen mixtures.

CONCLUSION

The intravenous or intramuscular administration of coramine can decrease the duration of postpartum narcosis due to barbituric acid drugs. This requires further confirmation.

The authors wish to thank the Ciba Company, Incorporated, New York for their generous cooperation.

THE PERSONALITY OF THE PHYSICIAN*

BY JOSEPH H PRATT, M D †

THE privilege of appearing before the students of this famous medical school as a lecturer in this annual course on the "Care of the Patient" is appreciated by me as it should be by any practitioner. The invitation, however, carried with it a special responsibility as the standard set by my predecessors has been so high. It has presented me with the opportunity and also the duty to devote considerable time to meditation in order that I might offer bread rather than stones. This task of preparation has been a pleasant one and has brought to mind happy memories. From the day I received the invitation from Dr Locke there has been frequently in my thought the picture of one we have loved and lost, Dr Francis W Peabody. The delightful address he delivered from this platform on the "Care of the Patient" has given to this course a special distinction. That essay should be read and reread by all medical students.

Only a month before Dr Peabody accepted the invitation to lecture in this course it was discovered that he was the victim of a fatal disease and he had been told the truth. He showed the stuff that was in him by acceptance of the situation and he went quietly about the daily business of living in a spirit of equanimity, without haste and without waste of time or thought.

When I was told of the shocking discovery made at the operating table I also learned that he was back at Northeast Harbor busy at his research work. He was engaged at the time on a fruitful study of the bone marrow in the anemias. Knowing he would not want sympathy but help I wrote at once and asked if I could not look up in the library some of the references he might wish to consult and prepare abstracts for him. In reply he wrote, "I am still poring over the microscope, but if any problems arise that want looking up I shall call on you."

Dr Peabody's lecture dealt chiefly with the

care of that large and neglected group of patients whose physical symptoms such as pain in various parts of the body, exhaustion and indigestion are the result not of organic disease but of a functional disturbance brought about by worry, fear and other forms of troubled thought. These are the patients who after a thorough physical examination are often blithely told by their doctor that there is nothing the matter with them. As regards the symptom for which they sought relief, they are told to forget it. It is all so simple and usually so ineffective. This reassurance, it is sad to relate, is about the extent of the psychotherapy still practiced by the average physician. It may be that at the very moment the doctor is giving the advice to forget it the poor patient is racked with pain or is so dizzy he can scarcely stand. Is it any wonder he turns in despair to Christian Science or to osteopathy? He knows he is sick in spite of the calm and cheerful assurance of the doctor to the contrary. The irregular practitioner, ignorant though he be of any knowledge of the body and its disease, inspires in the patient faith in the treatment offered, no matter how absurd it may be. The result is that his fears are often soon dispelled. With agitation removed from mind and spirit the brain no longer sends out jangling impulses to all parts of the body, the symptoms vanish and the patient feels well again. He is not only cured but he is profoundly grateful to the man or woman who healed him. The stately temple to Mrs Eddy and her pseudoscience on Huntington Avenue is a visible testimonial to this fact and it is also a monument to the failure of the medical profession in New England to treat successfully the victims of the psychoneuroses.

From Peabody's lecture the student learns a truth that wise Ernst Wagner stated many years ago, namely, that we do not treat diseases but sick human beings. Flowing through Peabody's talk to students is a kindly spirit that came from his understanding heart. He shows clearly that it is not enough to search for evidence of organic disease by the most modern and scientific methods. If the scientifically trained physician stops his investigation when

he is satisfied that symptoms are not due to organic disease he is contented with a half truth and is not scientific enough

The subject that I wish to discuss with you this hour is the personality of the physician. No more fitting illustration of what the doctor should be can be found than that presented by my friend and pupil Francis Peabody.

For years prior to the day I heard his address on the "Care of the Patient" I had been a follower of Dejerine, the great French neurologist, whose simple common sense methods of psychotherapy I had employed with gratifying success. After the lecture I talked with Dr. Peabody in that anteroom at the left of this amphitheatre. His address doubtless made a deep impression on the audience but there was no evidence of unusual approval. In a few minutes the hall was emptied and we were alone. In answer to my inquiry he then told me that it was not Dejerine who had stimulated his thought during the preparation of his address but Dejerine's English disciple, T. A. Ross, whose book on the "Common Neuroses" Peabody held in the esteem it deserves. May I take this opportunity to urge you to read both authors. Dejerine's work on the psychoneuroses and psychotherapy translated by Jelliffe is unfortunately out of print. It is, however, still available in the original French (*Les manifestations fonctionnelles des psychoneuroses* Masson et Cie, Paris, 1911).

The last year of Dr. Peabody's life has been beautifully pictured in the memoir written by his father. There was no fight to escape from the dark valley into which Peabody saw him self rapidly swept. During the summer of that year I visited him in the quiet of his walled garden, and when the weather became cooler within the pleasant house. This had been the home of Wilhelm James, the very place in which the Gifford Lectures on the "Varieties of Religious Experience" had been conceived. He talked about my work and his work as if he had no expectation that his work was almost finished. He gave close attention to my plans for developing a clinic for advanced instruction in internal medicine and offered valuable suggestions. He approved fully of my idea of bringing selected assistants from the best clinics in Germany to my little clinic at the Boston Dispensary and saw clearly the advantage it would be to American students to rub elbows for a while with the best type of German assistants trained in the clinics of Krehl, Graef, and Morawitz. Only once did I hear him express any regret at the blotting out of his own plans for the future. Then he simply said, "Oh, if I only had five more years to complete my work," meaning the full development of his clinic and laboratory at the Boston City Hospital. All I could say in

reply was the well known quotation "It is better to travel than to arrive."

When his essay on the "Care of the Patient" was published in attractive format by the Harvard University Press, he sent me a copy. On receipt of my note of thanks for the gift he wrote me the following letter. It is written with a pencil and the lines slant

"There is no one whose approval of this little book I would rather have than yours—my scientific godfather." Many thanks for your note. I hope the little sermon may do some good. My great desire has been to have a medical clinic in which the highest type of scientific work was carried on in conjunction with the most human and sympathetic attitude toward the patients—a type of spiritual atmosphere that may be expressed by the word Christian (Of course I mean the true spirit of Jesus as expressed in the Gospels and not the so-called Christianity of the Evangelical churches.) It might be called a Christian Science Clinic. Best of all I think I see the germs of it developing. After all such is the best background for good scientific work.

He possessed that fruit of the spirit extolled by Osler under the names of imperturbability and equanimity. In addition to this he had acquired a closely related and even higher virtue in the scale of values which Saint Ignatius in his spiritual exercises termed indifference, meaning thereby that quality of mind and spirit characterized by the ability to live on a level higher than that of a mundane existence. At the same time he was so detached from any trace of self pity or even self-centeredness that he could throw himself wholeheartedly into his writing and the work of his assistants as well as into the activities of his family and friends, so far as he was physically able. There was a mastery of self that impressed everyone who talked with him as most unusual. It was in truth a fine variety of cheerful religious feeling, which this man of science experienced during the fifteen months when he found himself sitting face to face with death. When the end was near he was able to look back on the year and say that it was one of the happiest of his life. There was an apparent dissociation taking place between mind and body. As he grew weaker physically his thoughts seemed to become clearer and even more vigorous. "In rare moments of self disclosure he would speak, as if casually, of the approaching end. 'This is not so bad,' he said one day, 'as most people think.' It is like leaving behind one an old suit of clothes." * * * And yet again when the talk turned to religion 'It is a very simple thing. It just comes down to 'He that loseth his life shall save it.' So, without access of suffering or crisis of disease the tired body at last surrendered to the unwearied mind and unconquered will' (Francis G. Peabody). The

courage and cheerfulness with which he met disease and death were an inspiration to those who were privileged to call upon him during his illness. His friends left his presence uplifted and glad that here was a man for whom death had no sting. With him the victory of death was a triumph for the victim.

The first mental picture I have of Peabody dates back to the fall of 1906 when he was beginning his senior year in this school. I had offered that year for the first time a course in clinical research as an elective for fourth year students. I secured for a laboratory a room on the top floor of Building C. It was the first term of the School in its present location. Funds for this laboratory were willingly supplied by my chief, Dr. Reginald H. Fitz, and a "Diener" supplied. The word "Diener" was the term by which a laboratory assistant was known in Dr. Welch's Baltimore laboratory and also in Dr. Councilman's here in Boston. I mention this as indicating how dominating in American medical science at that time was German influence.

Peabody, perplexed as to what he should study during the final year of his medical course and uncertain as to his future, visited Prof. Fitz at his Manchester home for advice. Dr. Fitz told him of my new course in clinical investigation and advised him to take it. I know Peabody consulted at least one other man, an eminent laboratory investigator, who expressed doubt whether I would be able to devote time enough to the proposed study to justify the sacrifice of the excellent clinical opportunities that would be lost if even a month were spent in laboratory research.

Only recently I learned from Prof. Peabody's biography of his son that Dr. Fitz had difficulty in obtaining the consent of the faculty to my new enterprise. It was without doubt generally felt by the clinical teachers, with the exception of Dr. Fitz, that it was a foolish undertaking because the view was then held that laboratory science played a mighty small part in the practical training of future practitioners. What had a laboratory research in bacteriology to do with the practice of medicine? The students had had the first two years of their course devoted to the laboratory, what they needed in the fourth year, most clinical teachers held, was not laboratory work but every bit of clinical instruction they could get. At the time of which I speak there was a great gulf fixed between the scientists and the clinicians in this school.

I mention this incident in such detail to show that it took courage for Peabody to follow a course that must have been frowned upon by every clinician he consulted excepting Dr. Fitz. We took a bare room in the newly opened build-

ings and fitted up a bacteriological laboratory. The problem assigned to Peabody was to isolate typhoid bacilli from the dejections of typhoid patients by the use of new methods. The program I proposed to him would have repelled most students. He had to go from his home in Cambridge each morning to the Massachusetts General Hospital and there gather up the collected feces of typhoid patients and bring them out to the school. The distance from the Massachusetts General Hospital to Longwood Avenue seemed much longer in those days when one had to travel by electric cars. Arriving at the school he had to make all the culture media, and to do all the work aided only by an untrained laboratory boy. He completed the research and we published it under our joint authorship, first in German in the *Centralblatt für Bacteriologie*, and later in English. Strange to relate the work yielded to him results of practical importance that we did not anticipate. The knowledge gained of the bacteriology of the typhoid bacillus enabled him, while an interne at the Massachusetts General Hospital, to isolate this micro-organism from the blood of the ear in all of five cases of typhoid fever admitted during the first week of the disease. Knowledge of what he had accomplished in the matter of early diagnosis spread rapidly. As a consequence while yet an interne he was asked to present the results of his hospital study before the Section of Medicine of the American Medical Association. This he did at the meeting in 1908. I can recall no other interne who has reported original work in clinical medicine at a meeting of our national society.

Peabody's gratitude to me for starting him on investigative work was far greater than I deserved, and time did not lessen it. Although he stood first in his class in the medical school he confessed to me years later that he felt no enthusiasm for the work during the first three years and that he lived laborious days simply from a sense of duty. In a letter written after the onset of his last illness he stated that it was I who first showed him "the joy and satisfaction of seeking new truths." In looking back over my life it is a source of pride to know I had some part in the education of this distinguished physician. At the same time I recognize the truth that all I did for Peabody was to act as a transmitter of something I had received in abundant measure from my own masters in medicine. Goethe in his conversations with Eckermann brought out the point clearly that when a man deducts the debts he owes to great predecessors in his field of work and to his own teachers and fellow-workers there is not much left that he can call his own. In my own case I know this is true. The happiness and satisfaction in my life work have been due to my

good fortune in being closely associated with a series of great men during my formative years who stamped me with the impress of their strong personalities. Three men who instilled into me a genuine love of medical investigation were teachers in this School Dr William T Porter Dr William T Councilman, and Dr Frank B Mallory, and I am glad of this opportunity to express my indebtedness to them.

You may be surprised to know that at the time I entered the Harvard Medical School Yale graduates were more highly favored than those from across the Charles. That is, if they had taken, as I had, the course in physiological chemistry given by Prof Chittenden, the first man to establish in America a laboratory for physiological chemistry.

At our introductory lecture in physiology the announcement was made by Prof H P Bowditch that if any members of the entering class had taken Prof Chittenden's course they would be excused from the regular work in physiological chemistry but would be expected to do special work in physiology in his laboratory. There I met the young assistant professor of physiology, Dr William T Porter. He took me through the well-equipped laboratory and showed me different forms of the elaborate apparatus used in his researches. Then he told me I could work with him on any one of three problems which he explained, each requiring for its solution different types of instruments. He added that if we got results worth reporting we would publish them jointly. The intimate association I enjoyed that year with Prof Porter was of great value to me. When I began to work with him I looked upon the original investigation we undertook simply as furnishing an opportunity to learn how to tie ligatures rapidly and securely, and to keep clean the field of operation by proper sponging. My ambition at that time was to be what Dr Oliver Wendell Holmes called "a drawer of blood and a hewer of members." In the course of time Dr Porter aroused my curiosity and I became interested in the experiments. He was making important studies on the work of the heart, a continuation of the fine Arbeit he had published in *Pflüger's Archiv* two years before. Through him I sensed the dignity of scientific research as exemplified by Heidenham and his assistant Hürtle under whom Dr Porter had worked in the Breslau Laboratory. His description stamped a picture on my mind of Heidenham walking to and fro on the shaded path in the park which adjoined his laboratory, hurried in thoughts bearing on the investigations in progress. From Dr Porter's enthusiasm I gained some slight intimation of the joy of creative work. Following the path on which he started me I discovered later the fun that comes from exploring the unknown.

The man whom I look upon as my father in

medicine was also a professor in this school—Dr William T Councilman. I was his assistant for four of the happiest and most profitable years in my life. From the day I first worked in his laboratory to the very end of his life he was a loyal friend and always willing to help with wise counsel. Great in science he was still greater as a man. Read Cushing's sketch of him for there you will find a faithful picture of a strong and delightful personality. He was a modest, kindly, vigorous man with an open mind, who loved nature and his fellow man. To his students he brought the inspiration and knowledge he had gained from his own great masters—Martin in Baltimore, Conheim in Leipzig, and later Welch, who regarded Councilman as his dearest friend. His every thought and act were honest and sincere. He worked for the good of this school and for the good of his assistants and never for selfish ends. In the last decade of Mr Eliot's régime Dr Councilman's clear vision and unselfish labors did much to elevate this school toward the eminent position it occupies today in the world of medical education and research. Largely through Dr Councilman's efforts the barrier of prejudice and misunderstanding which existed between the laboratory and the clinic in this university was broken down.

When Councilman arrived here from Johns Hopkins he found a young assistant in the department by the name of Mallory whom he recognized as a man of exceptional ability. Soon Mallory became his right hand man and they worked together for many years producing a series of important monographs on diphtheria, cerebrospinal meningitis and other subjects. When the fine new pathological laboratory of the Boston City Hospital was opened in 1896 Dr Mallory was placed in charge of it. In June of that year, having just completed Dr Welch's course in pathology at Hopkins, I began to work in this new laboratory and then first came in contact with Dr Mallory. His name was already well known to us in Baltimore, and we had heard Dr Welch say that Weigert in Germany and Mallory in America led the world in the technique of pathological histology. For two years following my graduation I had the good fortune to work under Dr Mallory and to be one of the earliest of that long line of young men who have had the benefit of his personal instruction in observation and in the preparation of organs and tissues in such a way that careful observations of microscopic details were possible. That was the best kind of so-called elbow teaching. He influenced us more by example than precept. Most investigators when placed in charge of a large laboratory degenerate into administrators and organizers of the actual work which is done by assistants. Not so Mallory. From the day I first met him in the laboratory until the present I

have always found him busily at work unraveling the secret of the histological or gross specimen before him. The impact of his personality upon that of his assistants is as great as any man I have ever known. He created a definite school in pathology, and without conscious effort impressed his methods and his point of view upon his pupils. His enthusiasm for his work has never waned and it has a contagious quality about it that few can resist. His problems seem to exhilarate him and I feel sure that his attitude of mind toward his work has made it an engrossing pursuit compared with which the amusements of ordinary men would be dull indeed.

When discussing the particular problem upon which he is engaged he conveys to his hearer the feeling that nothing could be more interesting than its solution. Long may he live to work in the noble institute of pathology that bears his name.

The addresses given to preceding classes by the lecturers in this course have been of such value to student and practitioner alike that they have contributed distinction to the daily work of the physician. They have tended to raise the dignity of the art of medicine and in so doing have filled a need. Not a few of the ablest graduates of this school in recent years have felt during their intern days that the worst thing that could happen to them would be to earn their living by private practice, so great has been the lure of laboratory and teaching clinic.

Some of the lectures in this course have been collected and published in a volume entitled "Physician and Patient." Busy with prescribed studies it is possible that some of you have not read this helpful book.

Within recent years the study of personality in its relation to medicine has been revived and it appears that the old humanities and the new sciences are to be united. If so, Plato and Aristotle may once again join Hippocrates and Galen as the fathers of medicine. My old teacher, Prof. Kiehl, in a recent address on personality and disease-forms says that while the medicine of the recent past rests on natural science as its sole foundation, that of the future will undoubtedly be built partly on natural science (*Naturwissenschaft*) and partly on psychology, metaphysics and ethics (*Geisteswissenschaft*). This statement which may sound revolutionary should carry weight for it is made by that undoubted leader in clinical medicine and pathological physiology, Rudolf Kiehl. The great pioneer in this new field of medical investigation dealing with the relation of personality to disease is no less a man than Friedrich Kraus of Berlin from whom in his early years your dean, Dr. Edsall, obtained light and leading. Kraus's first studies on personality as it relates to clinical investigation appeared more

than a quarter of a century ago. Since his early work important studies on personality and character in their relation to medicine by himself and by others have been coming from the press in increasing number. A new science, characterology, like a new star in the firmament, has appeared. The word "characterology" is not listed even in recent English dictionaries except the latest, the 1934 edition of Webster's International.

Professor Kiehl in the last edition of his famous work on pathological physiology stresses the importance of personality in the study of the sick man. The man is a unit, he says, meaning a psychophysical entity, and this man is sick. You as practising physicians will be dealing always with a personality in the form of your patient who is being acted upon at the time he seeks your aid by some external or internal disturbing force. For example, the external disturbance may be a nail in the foot or, the internal disturbance, one caused by an ulcer of the stomach or painful thoughts. Let me take the first of these examples to make my meaning clear. The patient has a nail in his foot. He pulls it out himself. Why does he come to the doctor? Very likely because he fears infection, possibly lockjaw. Your whole duty as a doctor does not end in giving him antitoxin. It is equally your duty to remove from his mind the fear produced by this injury to his body.

The problem of determining what is disturbing the personality of your patient presents itself every day at the bedside of every patient to every practitioner. Each problem is different and no matter how long you practise the healing art the same problem is never repeated, for the same personality is not found twice in the same state of being and subjected to exactly the same disturbing irritant. Kiehl believes that when pathological physiology has advanced sufficiently to explain the effect of injury upon personality, pathological physiology will become a part of the *Geisteswissenschaft*.

It is well to remind ourselves from time to time that the word cure comes from the Latin *cura* and the cure of the patient originally meant simply the care of the patient. "The priest had the parish for his cure, the physician the sick for his" (James Jackson). In this original sense we should continue to cure our patients until they recover or until death closes the scene. Toward the end of a fatal illness the family of the patient may need our cure more than does the one who is dying. The importance of caring for the patient to life's end has been emphasized by one who has previously lectured in this course, our beloved Dr. Alfred Worcester, a man who practises what he preaches.

The ancients rightly styled man a microcosm or little world within himself. The advances made in psychology have emphasized the truth of

this old view. Back of our conscious minds is the undiscovered country of the unconscious. Man has prided himself that he is guided by reason. One period of history called itself the age of reason. The truth is quite otherwise. Modern psychology teaches that the color of our thoughts and the motive power behind our actions are more influenced by the emotions than the reason. Of this drive of the affects we are usually quite unconscious. Man's free will to think and to act is inhibited or strengthened by the impulses resulting from a multitude of influences inherited or acquired. Often in us some virtue or vice passed on by an unknown ancestor lives again.

Fortunately environment has great influence in directing and strengthening native gifts. The impact of the personality of a great teacher on the personality of his students and disciples has wrought wonders in transforming lives and creating powers which some students in turn have been able to pass on to others. This transmission of spiritual and intellectual energy has been exhibited many times in the course of medical history. The seed sown by an inspired teacher often falls on sterile ground. It is true, but when it lodges on fertile soil it may bring forth a hundred fold.

In the favoring atmosphere of this medical school the personality and character of the carefully selected group that have the privilege of studying here should grow apace if you that make up the student body are receptive to the good influences that are acting upon you. These influences are like radio waves and to perceive them you must have a recording apparatus that is correctly tuned. True success as a physician is largely dependent on personality and character. In the sick room what you are may speak so loud that the patient cannot hear what you say.

The real Harvard Medical School does not consist of these stately marble buildings. They are simply the outward sign of the real medical school which is a house not made with hands. Its builders have been those master minds of medicine who have lived and labored far it since the foundation in 1783.

The Father of the Harvard Medical School John Warren, possessed a personality of a very high type, and the record of his life is an inspiring one. "That we may do justice to his fame," said James Jackson, "let us make it useful as was his life. Let us all, and particularly his professional brethren, strive to imitate his virtues." You can learn to know the real man by studying his biography written by his son Edward Warren. No teacher was ever more self-taught than John Warren, and few have had more obstacles to overcome. His plan to form a medical school aroused the active opposition of all the leading physicians in Boston. They so misunderstood the man that in

his efforts to help students they saw only an attempt at personal aggrandizement. They showed their resentment. The unanimous vote of the local medical society prevented Dr. Warren from giving clinical instruction in any hospital from the founding of the school in Cambridge in 1783 until its removal to Boston 1810, a period of twenty-seven years. As a result the school in Cambridge was a poor weak thing. There were few students and usually only one graduate a year, never more than two. Not only were his motives wrongly interpreted by his fellow practitioners in Boston with the result that they became as a group hostile to him and to the School but his medical colleague in the faculty of three, Dr. Benjamin Waterhouse, became his enemy. It is sad indeed that Dr. Waterhouse, a man gifted by nature and equipped with the best medical education of any American of his generation should have been blind to Dr. Warren's virtues. His antagonism against Warren grew with the years until it finally led to inexcusable acts which resulted in his dismissal from the school. We have the testimony of James Jackson that Warren's nature "was ardent, most affectionate, most generous. Fair and open himself, he learnt to distrust others only from experience."

Soon after John Warren entered the army at the outbreak of the Revolutionary War his ability attracted the attention of Dr. John Morgan, the Surgeon General. Although a very young physician, Warren was placed by Morgan in charge of military hospitals, first on Long Island and then in New Jersey. Two years after his promotion to the rank of hospital surgeon, Morgan's successor, William Shippen, appointed Warren chief of the army hospital in Boston in a position he held until the end of the war. The opportunities thus furnished for the study of anatomy and surgery enabled Warren to develop his rich talents.

Not only were Morgan and Shippen the founders of the first medical school in America, which later became the medical department of the University of Pennsylvania, but through the aid and support given John Warren, may be truly regarded as the grandfathers of the Harvard Medical School.

When John Warren began his life work in Boston he alone was actively interested in medicine as a science. We have the testimony of a contemporary, Ephraim Eliot that the Boston physicians were jealous of one another and like oil and vinegar they would not unite. "They did not love each other," says Eliot, "and all were determined to put down Warren, but they could not, he rose triumphant over them all."

John Warren fortunately lived to see the establishment of a vigorous medical school in Boston with an harmonious faculty. His eldest son John Collins Warren, together with another

young man, James Jackson, carried on the work John Warren had begun. John Collins Warren succeeded his father as professor of anatomy and surgery and like him became the leading surgeon in New England.

The Massachusetts General Hospital is the realization of John Warren's dream. It was he that secured an initial bequest from William Phillips to be paid to the trustees "as soon as they shall determine to begin the work." Unfortunately John Warren did not live to see even the laying of the corner stone, which was done with much ceremony three years after his death. On entering the old Bulfinch Building of the Massachusetts General Hospital it is well to call to mind the memory of two men, John Collins Warren and James Jackson, who, inspired by John Warren, founded the hospital by their joint labors. These two men who did so much for this school, for the Massachusetts General Hospital, and for the elevation of the medical profession in this country, have shown their personalities in their published works, and in their writings their spirit survives. Dr Jackson still lives in his *Memoir of James Jackson, Jr* and the "Letters to a Young Physician" and Dr J C Warren in his biographical notes which are incorporated in the biography prepared by his brother. They brought to this medical community a spirit of peace, unity, and concord. Writing in 1867, Dr Oliver Wendell Holmes said, "No man ever did more, if so

much, as Dr Jackson to produce and maintain the spirit of harmony for which we consider our medical community as somewhat exceptionally distinguished. If this harmony should ever be threatened I could wish that every impatient and irritable member of the profession would read that beautiful, that noble Preface to the 'Letters' addressed to John Collins Warren. I know nothing finer in the medical literature of all time than this Prefatory Introduction." This spirit of harmony still characterizes our medical community nearly seventy years after Dr Holmes wrote the words quoted. Let us do honor to the men who first exhibited it here, John Warren, John Collins Warren, and James Jackson.

The men I have selected to illustrate the qualities of heart and mind that make the personality of the physician successful in his profession have all contributed much to this school. The more you study them the greater will be your admiration for them. It is my hope that you may make them your friends. In the library they, through their writings, are always ready to instruct you. Learn of them. In gaining instruction you may, I trust, also receive inspiration. In developing your own personalities you would do well to imitate the virtues of the succession of physicians from John Warren to Francis Peabody who have labored here for the advancement of the science and art of medicine.

ABDOMINAL COMPRESSION AND VAGINAL TAMPONADE IN THE TREATMENT OF ABRUPTIO PLACENTAE*

BY ROY J. HEFFERNAN, M.D.†

ABRUPTIO placenta is one of the major catastrophes of obstetrics. As soon as the diagnosis is made or *suspected*, the patient should be hospitalized. Watchful expectancy, an admirable policy in many abnormal obstetrical conditions, has no place in the treatment of premature separation of the placenta. Measures should be promptly instituted to (1) control hemorrhage, (2) improve the patient's general condition, and (3) empty the uterus. As soon as an abdominal and pelvic examination has been made, if the patient is bleeding, externally or internally, a firm Spanish windlass should be applied to the abdomen with a tight T-binder to the perineum, and morphine sulphate, grain $\frac{1}{4}$, administered subcutaneously. This simple procedure, advocated years ago by the Dublin School¹, usually stops the hemorrhage and permits a careful unhurried analysis of the case,

so that the safest type of delivery may be selected.

Meanwhile the acute anemia or shock so often present should be relieved by blood transfusion, external heat, and glucose or saline solution by vein and hypodermoclysis. Needless to say no active operative intervention should be attempted until the patient's general condition warrants it.

In recent years cesarean section has been advocated as the best treatment for the bleeding complications of the third trimester of pregnancy, namely placenta previa and abruptio placenta. For most cases of placenta previa this is good practice. In this condition delivery through the pelvis is fraught with greater danger to both mother and baby. Rupture of the uterus and extensive lacerations of the vascular friable cervix may occur in the best hands. In abruptio placenta, however, the integrity of the lower segment and cervix has not been compromised and the conservative management of more of these cases is desirable. Unquestion-

*Read at a meeting of the New England Obstetrical and Gynecological Society at the Carney Hospital Boston November 13, 1935.

†Heffernan, Roy J.—Visiting Gynecologist and Obstetrician, Carney Hospital. For record and address of author see "This Week's Issue" page 381.

ably if the parturient is at or near term with an undilated cervix, the baby alive, and symptoms of severe abruptio placentae, an abdominal delivery is indicated. Again, if the symptoms are sufficiently severe to warrant a diagnosis of uteroplacental apoplexy, with hemorrhage in filtration of the myometrium (the so-called "Concealed uterus"), a cesarean should of course be performed, followed by hysterectomy if the uterus will not contract.

However, if the symptoms are less marked, or occur many weeks before term so that the baby is very premature, or dead or if the patient is extremely toxic or anemic and not a good operative risk, or if labor has started so that there is some dilatation of the cervix the application of a firm Spanish windlass, with a tight vaginal tamponade or Voorhees bag supplemented when necessary by blood transfusion and other supportive treatment, will usually result in the completion of the first stage of labor with very little additional hemorrhage so that delivery through the pelvis may be safely accomplished. Before packing, the patient should be prepared with scrupulous care and the bladder emptied. If narrow (one inch) iodiform gauze is not available, plain gauze may be used after a thorough soaking in two per cent aqueous solution of mercurochrome. The cervix and vagina should be packed as tightly as possible.

These points can best be illustrated by describing briefly the following cases.

CASE 1 Mrs. J. aged 25 para 2

First pregnancy interrupted three weeks before term for severe pre-eclamptic toxemia. The last period was January 11 with the expected date of confinement October 13. In June and July the patient showed a slight trace of albumin in the urine and the blood pressure rose from 120/70 to 144/94. On August 15 while working about the house the patient felt a sudden sharp pain to the left of the umbilicus began to draw and felt faint. When seen at her home a short while later the patient was flowing profusely passing large clots and the abdomen was firm and tense pulse 96 blood pressure 134/88. A firm Spanish windlass and T binder were applied, a quarter grain of morphine sulphate was administered and the patient transferred to the Carney Hospital. The cervix was found to be one finger dilated and half effaced. The cervix and vagina were firmly packed with narrow iodiform gauze and the Spanish windlass continued. There was no further bleeding. One hour later active labor started and after five hours the pack was removed and a 3 lb., 1 oz. baby delivered followed by the placenta, which showed the characteristic depression filled with old blood clot. The uterus contracted well and the patient made an eventual recovery returning to her home in twelve days. The baby gained slowly and was discharged in four weeks.

CASE 2 This is interesting because trauma was apparently the cause of the separation.

Mrs. N., aged 35 a primipara, had her last period January 26. Blood pressure and urine were nor-

mal for four months. On June 10 the patient was in an automobile accident and sustained a severe blow on the abdomen. She had considerable abdominal pain with moderate flowing which subsided after three days during which the patient was confined to her bed and received four injections of morphine sulphate grain one-sixth. After the fourth day the patient was allowed to be up and about. There was an occasional slight bleeding and three weeks later the abdominal pain recurred with profuse flowing. This subsided promptly under the treatment outlined above. Five weeks later the patient had a similar experience. The general condition remained good blood pressure remained normal and urinalysis was negative. There was slight staining with occasional flowing off and on until September 4 when a profuse flow with clots made it necessary to transfer the patient to the Carney Hospital. The fundus was two fingers above the umbilicus the fetal heart right and below rate 144 the cervix one finger dilated. The pulse was 108 blood pressure 110/64 the red count 3 200 000 with hemoglobin of 60 per cent. A firm Spanish windlass was applied and a number 5 Voorhees bag inserted in the cervix. All bleeding stopped immediately. In one-half hour labor pains started and the bag was expelled three hours later. A 3 lb 3 oz baby was delivered by breech extraction. It expired after three hours. The placenta showed a characteristic punched-out area four inches in diameter extending to the margin of the placenta, and a considerable amount of old blood and blood clots was expelled. The uterus contracted well and the patient was discharged in good condition except for a moderate secondary anemia, on the fourteenth day.

CASE 3 Complete separation with internal concealed hemorrhage

Mrs. P., aged 45 para 12. Nine children living and well. All previous deliveries normal. The expected date of confinement was November 25. On November 7 the patient fell on the cellar steps and struck her left side. After resting awhile she felt well and continued to do her housework. She had no pain or bleeding until the present date November 10. Early that morning she went to the bathroom and while voiding felt something "drop" in the lower abdomen, but experienced no pain. Shortly after this she fainted. Thinking that this was due to hunger she ate some food but fainted again shortly after. She returned to bed and fainted again. She then began to experience pain in the right side of the abdomen, and felt nauseated and weak. She observed that her abdomen was increasing in size and said she felt as though the fetus were being pushed upward. In the afternoon she called Dr. Fred Costanzo, who found her in shock, her face ashen white and drawn the abdomen tense and boardlike, with the blood pressure 100/60 and the pulse rate 100 of poor quality. There was no sign of any vaginal bleeding or staining. She was transferred to the Carney Hospital and I saw her in consultation a short while later. The general condition was as stated above, the r.b.c. 3 000 800 w.b.c. 14 000 hemoglobin 60 per cent. The abdomen was tremendously enlarged with a rounded mass larger than a fetal head projecting from the upper part of the fundus. The cervix was one finger dilated and well effaced, the membranes were intact there was no bleeding and no evidence of blood serum in the vagina. A firm abdominal binder was applied and the vagina packed tightly with iodiform gauze. Seven hundred cc of blood were given by the citrate method, and 1000 cc of five per cent glucose and saline solution administered by hypodermoclysis. The patient's general condition improved and four hours later the pack

was removed and she delivered spontaneously a 6 lb stillborn fetus, immediately followed by the placenta, the entire surface of which was covered with old and new blood clots. Apparently there had been a complete antepartum separation of the placenta. Several very large old clots, sufficient to completely fill a large basin, were expelled and a moderate postpartum hemorrhage occurred. This was checked by pituitrin and ergot, after which the uterus contracted well. Six hours later the pulse had risen to 140, was of poor quality, the patient felt nauseated, and the blood pressure had dropped to 84/40. Another indirect transfusion of 600 cc of blood was given, and the patient made a slow but steady improvement, and was discharged in fair condition on the fourteenth day.

CASE 4 Mrs M, aged 33, para 3

First baby was delivered with high forceps and died five hours later. Second baby was hydrocephalic, and delivered at the eighth month. The last period was October 15, probable date of confinement July 22. The pregnancy was normal until the eighth month when a slight trace of albumin appeared, with a few headaches and moderate edema of the ankles. The blood pressure remained normal. On June 12 she was awakened at four o'clock in the morning by a feeling of abdominal discomfort and backache. On going to the bathroom she observed that she was flowing profusely. Violent fetal movements were noted, which ceased completely after a few minutes. I saw her a short while later at St Margaret's Hospital. The fundus was considerably larger than it had been four days previously, there was a steady moderate flow of bright red blood, the fetal heart could not be heard, the uterus was tense and firm and the abdomen tender. The cervix was two fingers dilated, and partly taken up. The patient looked drawn and pale, blood pressure was 104/56, the pulse 128, of poor quality. A firm Spanish windlass was applied and the vagina packed tightly with iodoform gauze. Five hundred cc of blood was then given by the citrate method. The patient's general condition improved and the pulse dropped to 104. After two hours the patient's condition remained about the same, and as active labor had not started, she was given one minim of pituitrin every twenty minutes. After the second dose labor pains began and four hours later the patient was delivered of a 6 lb, 4 oz stillborn fetus. The placenta had apparently undergone complete separation as it immediately followed the fetus, and the maternal surface was covered with clotted blood. A considerable amount of fluid and clotted blood followed the placenta. The uterus did not respond well to massage, intramuscular pituitrin and ergot, but after the injection of three minims of pituitrin, diluted with four cc of warm salt solution, by vein, the uterus became firm and remained so. The patient made a good recovery and was discharged on the twelfth day.

CASE 5 Mrs K, aged 37, para 1

Last period July 12. Expected date of confinement April 19. March 14 the patient had no toxic symptoms, the blood pressure was 130/80 and urinalysis was negative. The fundus was three fingers below the ensiform, with the fetal heart left and below. Two days later the patient retired with a headache and a feeling of general malaise. At six o'clock the following morning she awoke to find herself flowing profusely. She was transferred to the Faulkner Hospital, where she arrived in a condition of shock, with a pulse of 130, of poor quality, marked pallor, and flowing profusely. The abdomen was firm and tender. No fetal heart sounds could be heard. The cervix was two fingers di-

lated, well taken up, with the vertex dipping into the inlet. A firm Spanish windlass was applied, the vagina packed tightly with gauze impregnated with two per cent mercurochrome solution, and glucose and saline given intravenously. After some delay in securing a donor, a transfusion of 700 cc of blood was given. Labor had apparently started before the patient reached the hospital, and it progressed with very little further bleeding for eight hours. The patient's blood pressure had risen to 140/90, her color had improved, and the pulse was 96, of good quality. The pack was removed, cervix found to be five fingers dilated, and a 6 lb, 12 oz stillborn fetus was delivered by mid forceps. The placenta showed the characteristic changes of abruptio placentae involving more than half of the maternal surface. The uterus contracted well and the patient was returned to bed in fair condition. She made an uneventful recovery, except for a slough of the antecubital space which did not fully heal for two months. She was discharged from the hospital in good condition on the sixteenth day.

CASE 6 Mrs C, aged 42, para 5

First baby delivered by forceps, others normal. All previous children living and well. This patient was seen at St Margaret's Hospital, in consultation with Dr John A. Foley on May 14. During the past two months she had shown signs of a moderate pre-eclamptic toxemia, with a blood pressure ranging between 140/90 and 150/100, a small amount of albumin in the urine, occasional headaches and dizziness, and increasing edema of the feet and legs. The expected date of confinement was May 24. The patient had been in labor for four hours and was having regular pains every five minutes, lasting about forty seconds, when she suddenly experienced a sharp pain near the umbilicus, felt weak and dizzy, and fainted. Moderate flowing ensued, and the pulse increased to 118. The patient appeared pale and anxious, the abdomen was very large and suggested a multiple pregnancy. She complained of constant backache and dull constant pain in the abdomen. The uterus between pains was relaxed and not firm and tense, as it usually is with abruptio placentae. A fetal heart could be heard in the right lower quadrant at the rate of 136. Rectal examination showed a head engaged, with the cervix four fingers dilated, membranes intact. A firm abdominal binder and tight T binder were applied, with immediate cessation of the flow. The patient's general condition improved, the pulse dropped to 104, and preparations were made for a blood transfusion. Gas was administered with the labor pains, which increased until in one hour they resembled second stage pains. The cervix was then found to be fully dilated, and a 6 lb, 12 oz child was extracted with mid forceps. A second baby, which weighed 7 lbs, 1 oz, was then delivered by version and breech extraction. Both babies were alive and well. Under the usual stimulation the fundus contracted well and a large placenta, showing a depression four inches in diameter on the maternal surface, was expelled. The patient's general condition was fairly good, so that a transfusion was not given. She made a good recovery and returned home with her babies on the fourteenth day.

CASE 7 Mrs C, aged 29 years Para 1

This patient was seen in consultation with Dr Joseph McSweeney at the Somerville Hospital. The expected date of confinement was November 19. Two weeks before admission the blood pressure had risen to 140/100 and the urine showed a slight trace of albumin. There were no other symptoms, and the usual treatment for a mild toxemia was instituted. On September 29 the patient had a severe chill, but the temperature remained normal. Shortly after

that she noted a cessation of fetal movements, and developed a slight edema of the ankles with occasional blurring of vision and headaches. The urine showed a trace of albumin. On October 5 she experienced a sudden flow of blood soon followed by the onset of labor pains. She noted that a gush of blood would occur with each contraction of the uterus. She was then transferred to the Somerville

The Spanish Windlass. 1. Long abdominal bladder, perineal bladder and wooden rod in position. 2. Tightening the bladder by twisting the rod. 3. The Spanish Windlass applied.

Hospital. When seen the pulse was 94 of fair quality there was moderate pallor blood pressure 150/110 with the fundus three fingers above the umbilicus, firm and tender and the patient having thirty-second contractions every five minutes. There was a steady moderate flow of blood from the vagina and the cervix was two fingers dilated and well taken up with the vertex high. The fetal heart could not be heard. A firm Spanish windlass was applied and a number 5 Voorhees bag in-

serted in the cervix, with a half pound weight attached. Except for very slight oozing this controlled the bleeding. The patient's general condition remained fair and preparations for a transfusion were made. She had been nauseated for several hours and had not retained fluid so 1000 cc of five per cent glucose and saline was given by hypodermoclysis. Morphine sulphate grain 1/4 was given at the onset of treatment. The bag was inserted at 8:00 A.M. and was expelled three and a half hours later. Under ether anesthesia a premature macerated fetus was delivered by version and breech extraction. The placenta showed an area of separation involving about one-third of the maternal surface with old blood and clots in one area indicating a probable first slight separation at the time of the chill three days before. The uterus reacted well and the patient was returned to bed in fair condition. She made an excellent recovery and was discharged to her home on the twelfth day.

SUMMARY AND CONCLUSIONS

Compression of the uteroplacental sinuses by means of a Spanish windlass supplemented by cervicovaginal tamponade usually controls the hemorrhage in abruptio placentae.

This affords time for transfusion and other measures to improve the general condition and seems to shorten and expedite labor.

Cesarean section should be reserved for cases seen at or near term, with an undilated cervix and a baby in good condition, and when true uterine apoplexy with hemorrhagic infiltration is believed to be present.

Seven cases of abruptio placentae are described demonstrating the value of the conservative treatment.

CASE REPORT

Inversion of the Uterus in Two Consecutive Pregnancies

BY ROGER E. STEWART, M.D.*

THIS patient was first seen by me on March 7, 1935, with the following history:

She was thirty-seven years of age and had been married four years. With her first pregnancy she had severe preeclampsia. The systolic pressure went to 230 mm, the urine holed solid, and there was retinitis and vomiting. A live baby weighing 5 lbs 4 oz. was secured by classical cesarean section. It was well developed. An undelivered fetus about three months in size was removed with the placenta. The postpartum course was uneventful. This delivery was on April 3, 1932. On October 3, 1933 she was delivered at term with a breech pres-

entation of a child that did not live. She was said to have been toxic with this pregnancy though her impression is that she was well throughout. While the obstetrician was waiting for the placenta without any credé maneuver it was extruded and quickly followed by a completely inverted uterus. The placenta was strongly adherent, and removed with difficulty. The uterus was restored at once manually. The patient's physician reported no shock or hemorrhage but the postpartum course was marked by a week of subinvolution, secondary anemia, and considerable mental depression.

The patient was seen by me early in her third pregnancy. In view of her age (thirty-seven) and previous history a cesarean section was thought to be her best chance for getting a live baby and also for her own survival. Her pregnancy was normal throughout. A low transverse cervical section was

Stewart, Roger E.—Assistant in Gynecology, Harvard U. T. Medical School. For record and address of all see "This Week's Issue" page 241.

performed at term, on August 17, 1935 at the Massachusetts Women's Hospital, and a vigorous seven and a half pound infant delivered. After waiting awhile, with no signs of separation of the placenta, slight *crédé* expression was resorted to. Shortly after this the placenta appeared in the incision. It quickly became extruded, and the uterus followed by completely inverting itself. The placenta was very adherent, and no point of separation could be found between its margin and the endometrium. Hysterectomy seemed the only way out, and had already been decided upon, when a slight area of separation appeared at one edge of the placenta. With considerable difficulty, the latter was removed, complete. There was no hemorrhage and no shock. The pulse ran at the rate of 112 during the induction of anesthesia, and remained at this level for forty minutes. It then gradually declined to 80 at the end of one hour and ten minutes. Her convalescence was uneventful, and she went home on the thirteenth day, postoperative.

COMMENT

While it is possible that the force used was sufficient to initiate inversion, it seems impossible as the pressure was so slight. The case is remarkable as an example of inversion, twice, with adherent placenta, but with apparently no shock or hemorrhage. It suggests some predisposition on the part of the individuals, in view of the many patients subjected to the *crédé* maneuver with all degrees of strength, experience, and judgment, in whom inversion does not result.

WIDESPREAD DECEPTION FOUND
IN ALCOHOL RUBS

Rubbing alcohol is frequently adulterated and misbranded, Federal drug officials find. In recent years rubbing alcohol compounds have been used widely for massage and bathing purposes. In December and January, activity in inspecting and testing supplies on the market have led to seizures involving 13,000 bottles, shipped under various names by dealers in the Eastern States. In all the seized rubbing compounds, the examining officials found isopropyl alcohol instead of Ethyl (grain) alcohol. One lot—in a class by itself—contained only two per cent of isopropyl alcohol, although the label on the shipping case claimed "70 per cent alcohol."

Isopropyl alcohol, relatively a newcomer among the commercial alcohols, is a by-product of the petroleum refining industry. It is known that this alcohol, when taken into the human system, is destroyed and eliminated very slowly, that is, its harmful effects are relatively persistent. For this reason, its use in foods such as flavoring extracts has been vigorously opposed by the Food and Drug Administration, and its use in drugs for internal use is subject to like attack.

W G Campbell, Chief of the Administration, stated recently, however, that the recent actions do not depend on proof of harmful effects from isopropyl alcohol. "It is not known whether harm does result from its external use," he said, "but Federal courts have repeatedly stated that one of the purposes of the Food and Drugs Act is to enable purchasers to buy foods and drugs for what they really are."

It was pointed out that it is misleading to label an isopropyl alcohol mixture in such a way that the package is an imitation of the well recognized rub

made up almost entirely of ethyl alcohol. This mislabeling is therefore in violation of the Food and Drugs Act. The purchaser does not receive the article he is led to expect. In some of the recent cases, the word "isopropyl" or the chemical symbols C_3H_7OH appeared in small letters on the labels, but the Administration does not consider either of these additions sufficient to inform the purchaser of the true nature of the article, especially in view of the prominent designation "alcohol" or equivalent expressions on the label. The Administration has taken the position that the labels of isopropyl alcohol preparations intended for external bodily use should show the exact nature of the article, without any accompanying words or trade names which tend to confuse the article with ethyl alcohol.

VIOLATIONS OF THE CAUSTIC POISON ACT

In the latest published list of judgments under the Act, three of the eight cases reported dealt with toys. One was a balloon outfit which included a dangerous acid to be used in generating gas for the balloon. Two cases resulted in taking off the market miniature educational chemistry outfits that included dangerous chemicals.

This Act requires that certain caustic or corrosive substances and preparations containing them in a specified concentration shall be labeled to bear the word "Poison", suitable directions as to antidotes, the common name of the poison, and the name and address of the manufacturer, packer, seller, or distributor. The substances are hydrochloric, sulphuric, nitric, oxalic, carbolic, acetic, and hypochlorous acids, salts of oxalic acid, potassium hydroxide, sodium hydroxide, silver nitrate, and ammonia water.—*Bulletin, U S Department of Agriculture*

TRACY B. MALLORY, M.D., Editor

CASE 22081

PRESENTATION OF CASE

First Admission. A fifty-six year old white American nurse was admitted complaining of soreness in the right upper abdomen.

Three weeks before entry she developed a vague dragging soreness in the right upper abdomen and flank. This was persistent but did not increase in severity. During the same time she noted shortness of breath with moderate exertion and some swelling of her ankles. She had frequent cramps in her calves at night. Other than a marked degree of flatulence there were no gastrointestinal symptoms. Her bowel movements were kept active by taking two laxative tablets three times daily. Three days before entry she was seized with severe non-radiating colicky pain in the right upper quadrant. There were no acholic stools, nausea, emesis or jaundice. The pain continued for two days and then abruptly subsided. Thereafter she felt quite well.

Twelve years prior to admission she had been ill with severe right upper abdominal pain associated with jaundice, nausea, emesis, and chills. At this time she was said to have passed two gall stones.

Her mother and one brother died of tuberculosis. Her father died of carcinoma of the rectum. One sister had diabetes.

Physical examination showed a short obese female weighing about 200 pounds. The tonsils were enlarged but not reddened. The heart and lungs were negative. The blood pressure was 150/75. The abdomen was full and rounded. Tenderness without spasm was elicited with moderate pressure in the right upper quadrant and high in the epigastrium. The liver was definitely enlarged and tender. There was no ascites. A few varicose veins were observed upon the legs and there was considerable edema of the ankles and feet.

The temperature, pulse, and respirations were normal.

Examination of the urine showed a specific gravity of 1.015 with a slight trace of albumin but was otherwise negative. The blood showed a red cell count of 5,160,000, with a hemoglobin

of 80 per cent. The white cell count was 15,500. 85 per cent polymorphonuclears. The nonprotein nitrogen of the blood was 39 milligrams per cent. A fasting blood sugar was 101 milligrams per cent. A Graham test showed no concentration of the dye.

The patient was discharged on the third day. *Second Admission*, four days later.

Two days after discharge from the hospital the patient was seized with severe, sharp right upper abdominal pain which radiated to the top of the right shoulder. There was associated nausea and emesis on the day of reentry. The pain persisted and increased in severity.

Physical examination showed no change since leaving the hospital except marked tenderness and spasm in both upper quadrants and in the epigastrium.

The temperature was 98.6°, the pulse 100. The respirations were 20.

Examination of the urine showed a specific gravity of 1.026 with a slight trace of albumin. The sediment contained 6 white blood cells and 50 red blood cells per field. The blood showed a white cell count of 13,000. The stools were brown and examination was negative.

On the second day a cholecystostomy was done. Except for a slight postoperative rise of 101° and an occasional rise to 100° during the second hospital week the patient's temperature remained normal. The postoperative course was good for about two weeks, at which time the patient gradually became jaundiced. An icterus index was 50 and a van den Bergh was 9.6 milligrams per cent. The icterus index gradually rose to 70. The nonprotein nitrogen of the blood was 58 milligrams and the serum chlorides were equivalent to 85 cubic centimeters N/10 sodium chloride. The urine showed a large amount of bile and the sediment contained a few red and white blood cells. The red cell count of the blood was 4,700,000 with a hemoglobin of 85 per cent. The white cell count was 23,700, 95 per cent polymorphonuclears. The stools were tan colored and gave a strong reaction to the guaiac test. Physical examination showed the patient to be dyspneic. There was edema of the extremities. The tongue was dry. The heart sounds were regular, rate 90, and the quality was only fair. The blood pressure was 110/80. The abdomen was soft, full, and shifting dullness was elicited in the flanks. There was no tenderness in the liver area. Her condition became progressively worse, she developed gallop rhythm, and finally expired on the twenty-seventh hospital day, about a week after the onset of her jaundice.

DIFFERENTIAL DIAGNOSIS

DR. HORATIO ROGERS. From the fact that this patient was a nurse we may take her history as above average in accuracy.

From the first episode we can say that she had a mild attack of something, presumably gallbladder disease, but if you look closely you will see that it is a little more than that. It was accompanied by dyspnea and swelling of the ankles, and followed by an unusual degree of weakness. This may or may not be an integral part of her present disease.

The sudden onset and abrupt termination of her attack are very suggestive of a mechanical cause.

From the past history we know that she has had gall stones, and I assume that she still has a pathological gallbladder, presumably the cause of this present attack.

Physical examination adds a few points. The blood pressure is not elevated. The liver is large and tender. The normal temperature rules out an acute inflammatory disease but the mild leukocytosis suggests the presence of some lesser degree of sepsis. The cholecystogram either was unsuccessful or indicates gallbladder pathology, I think the latter because it fits in with what we already know.

DR. GEORGE W. HOLMES: These films of course fail to show the outline of the gallbladder. You can see the edge of the liver quite well, and the edge of the kidney. I should think if the gallbladder had any dye at all it would have shown. It probably would be in this area and there is nothing there to suggest gall stones.

DR. ROGERS: If they thought they were dealing with a mild subsiding attack of cholecystitis or cholelithiasis in a poor risk patient they might perfectly well have discharged her on the third day.

The second attack is obviously more severe than the first, with marked systemic reaction and pain radiating to the right shoulder as in irritation of the right diaphragm, rather than radiation to the back as we should expect from gallbladder disease. There is still no fever.

Blood in the urine is confusing, since she has no jaundice, and the only other hint about kidney is that her original soreness was in the flank as well as the upper abdomen. It may be due to trauma from a catheter or it may be an important lead. The white count is lower than before, another point in favor of mechanical rather than inflammatory damage.

It is legitimate to speculate as to why a cholecystostomy was done. Not for jaundice, not for empyema of the gallbladder. The patient was a poor surgical risk but her symptoms were getting worse. The diagnosis was not entirely clear. An exploration was justifiable. The surgeon may have found that more surgery was desirable but unsafe, or that some inoperable condition existed.

Following operation she became progressively jaundiced in spite of a tube sewed into the gallbladder. That seems very queer. The chlorides are diminished, probably by loss of

bile from the tube and through vomiting. The tan color of the stools must indicate the presence of bile as well as blood. I cannot explain the blood unless her jaundice, brief as it seems to have been, accounts for it. At all events it is evident that the patient did not have a complete obstruction of the common duct.

A PHYSICIAN: I think we ought to know whether she drained any bile.

DR. ROGERS: I am taking "she did well for two weeks" as meaning that she did.

Jaundice with bile in the stools, unless it is hemolytic jaundice (and there is no shred of evidence for that) must be of intrahepatic origin and due to marked liver damage.

We are now dealing with a very sick patient with deep jaundice, dyspnea, edema and fluid in the abdomen. Is the fluid bile or ascitic fluid? There is no story of a sudden accident following operation to suggest the escape of bile into the abdomen. I shall assume ascites. Note that although the abdomen is now soft, nothing further is said of the enlarged liver. What has become of it? The spleen was never felt.

It seems to me that we have ample evidence of gallbladder and liver disease. Let us consider the common causes of death from gallbladder disease.

1 Mechanical accidents, such as rupture, or perforation of a stone into the intestine.

2 Infection.

3 Obstruction of the bile ducts by stone.

We have some evidence for 2 and 3 but none for 1 except the suddenness of events at first. Her last white count is consistent with some bile duct infection. We cannot rule out stones, but we feel sure the common duct is open. We know there is liver damage sufficient to cause deep jaundice and probably death, but what, besides low-grade infection, is causing the liver damage?

She is fifty-six. It is reasonable to suppose that she might have had some neoplasm with metastasis in the liver or even primary cancer of the liver or bile ducts, but there is little evidence for such a diagnosis. The acuteness of the symptoms, lack of gradual onset, and disappearance of the enlarged liver are all against cancer.

Viewing her disease as a whole, it seems to me the things that distinguish it from plain cholecystitis are the circulatory manifestations—edema, dyspnea, ascites. We know that a patient with portal cirrhosis may remain symptom-free as long as the compensatory circulation does not break down. But even a mild attack of cholecystitis might be enough to break it down by a superimposed biliary infection. Such a diagnosis would account for this patient's picture better than anything I can think of. It would explain the absence of a long history, the afebrile course, the jaundice, the circulatory

symptoms, and the fatal termination. It might account for the large tender liver at one examination and the presumed absence of a palpable liver thereafter. There should have been a palpable spleen, but perhaps this was missed because of the patient's obesity.

CLINICAL DIAGNOSES

Hypertension
Obesity
Cholecystitis
Hepatitis

DR. HORATIO ROGERS' DIAGNOSIS

Chronic cholecystitis
Mild acute cholangitis and hepatitis
Portal cirrhosis (fatty) of the liver

ANATOMIC DIAGNOSES

Carcinoma of the gallbladder with metastases to the peritoneum, liver, pancreas, mesenteric and retroperitoneal glands
Acute intrahepatic cholangitis
Operative wound
Drainage of abscess of the gallbladder bed
Ascites
Icterus
Bronchopneumonia
Focal necrosis of pancreas
Diverticulum of the duodenum
Cyst of the kidney

PATHOLOGIC DISCUSSION

DR. TRACY B. MALLORY. Dr. Rogers' line of thought ran very close to that of the physicians who were in charge of the case. The surgeon I assume, went right down to the gallbladder through adhesions and was unable to make an exploration. Certainly there is no note of the condition of the remainder of the peritoneal cavity or of the surface of the liver itself. As the patient progressively grew worse and became deeply jaundiced they began to think of cirrhosis and Dr. Bock was called in consultation. He differed from Dr. Rogers on one point. He thought if the patient had portal cirrhosis at this stage of the game she would have a small atrophic liver rather than a large one and consequently he was against the diagnosis of portal cirrhosis.

We found at autopsy a severe grade of liver damage in the form of diffuse cholangitis. The gallbladder was practically lost in a huge tumor mass, and on dissection it became apparent that the drain had never been in it but had been inserted into an abscess of the gallbladder bed. The tumor must have been growing very rapidly to have increased so much in size between the time of the operation and death which was less than a month later. The mucosa of the gallbladder was completely replaced with

shaggy tumor masses. The tumor had invaded deeply into the liver. There were metastases on the peritoneal surface, with terminal hemorrhagic ascites. We found nothing in the gastrointestinal tract to explain the positive guaiac in the stools. So that I think there is no question that she died of a primary cancer of the gallbladder with a secondary hepatitis. The bile ducts were perfectly free. There was no tumor in the head of the pancreas, also. We have had several cases in which we found it very difficult to decide whether cancer was primary in the gallbladder or in the pancreas. I think in all probability it is usually primary in the gallbladder in such a case. We have twenty-seven primary cancers of the gallbladder on record, and among those we found five in which the head of the pancreas also showed cancer. The other cases all showed metastases to the lymph nodes in the region of the head of the pancreas but no tumor was found in the pancreas itself. Most of the anatomical work tends to show that the lymphatics of the gallbladder run down over the surface of the pancreas but do not penetrate its substance.

Have you any comment, Dr. Allen?

DR. ARTHUR W. ALLEN. I would like to know whether any gall stones were found at autopsy or operation.

DR. MALLORY. No. I assume, however, as Dr. Rogers did, that she had suffered from gall stones in the past. Almost invariably cancer of the gallbladder is associated with stones or at least a history of stones.
